In several places, when referring to the feeding biology of some species, like *Pliocercus* (p. 43), the author states that it feeds on leptodactylid frogs. This use is no longer appropriate unless he means *Leptodactylus* to the exclusion of other so-called rainfrogs (genus *Craugastor* and *Pristimantis*; see Barrio-Amorós et al. [2013] for the rationale of using "landfrogs" rather than "rainfrogs"), now included in the family Craugastoridae or Strabomantidae (depending upon the authority followed).

After carefully reading the text, it appears that the author has not made much effort to modernize his information, but rather followed Savage (2002), Solórzano (2004), and a few others, with no real attempt to incorporate data from other recent sources, or even some more classic papers.

Perhaps most importantly, if this is a field guide to identify species, how are we supposed to identify them? Photographs can certainly help, but in many instances one needs a dichotomous key (like those in Köhler [2003] or Solórzano [2004]), especially if the guide is to be used in the field, and categorically one requires a description of the species, preferably as detailed as possible. Further, regardless of its utility, I do not really believe that the book can actually be considered a field guide; it is neither waterproof, nor does it have the flexible covers and convenient shape of typical field guides.

Even though the book is impeccably edited, as are all volumes published by Chimaira, I am surprised by the quality of the contents. I can enjoy the collection of photos, and can conveniently consult the distribution section but if I need to go deeper into any species I will always need the two classic "bibles" of Costa Rican snakes (plus a third for venomous snakes—Campbell and Lamar 2004). A better solution than a field guide would have been a Terrralog volume (another Chimaira book series with photos and maps but virtually no text!).

North American Amphibians. Distribution and Diversity

David M. Green, Linda A. Weir, Gary S. Casper, and Michael J. Lannoo. 2013. University of California Press, Berkeley, California (www.ucpress.edu). x + 340 pp. Hardcover. US $75.00. ISBN 978-0-520-26672-8.

STANLEY K. SESSIONS
Department of Biology, Hartwick College
Oneonta, New York 13820, USA
e-mail: sessionss@hartwick.edu

Amphibians ought to be of special concern to everyone. Not only are they of interest in terms of biodiversity and conservation, given water or moisture-dependent life cycles and vulnerability to environmental degradation, but they are also one of the best-known groups of vertebrates thanks to extensive studies at multiple levels of biological organization. Some species of amphibians are in decline or have possibly gone extinct due to recent human activity, and yet new species are being discovered every year, and molecular phylogenetic studies continue to reveal cryptic species in which single species are found to actually represent two or more distinct species. Continued resolution of phylogenetic relationships also means that scientific names are constantly changing. A critical component of our knowledge of amphibians is their precise biogeographical distribution. Field guides are very useful in this regard, as are official summaries and inventories, especially for professional herpetologists and other scientists. Also needed, however, are ways to emphasize the beauty and richness of amphibian biodiversity to general audiences as well as to specialists. The book reviewed here, edited by David M. Green and colleagues, fills this niche nicely.

It is a pretty book. The book contains excellent color photographs of every currently recognized species of North American amphibian (with only a single exception of a very rare salamander). Only one of the species (a frog) is represented by a pickled specimen rather than a photograph of the living animal. Another species is represented by a dish containing mere lumps of tissue and a museum tag, the best existing documentation of a very rare species of salamander. The book also includes a distribution map for each species, showing high resolution plots on topographic background maps—yellow dots on different shades of green and brown. The amount of verbal description for each species is kept to the essential minimum—brief, but authoritative, most of it from Lannoo (2005) with original authors listed.

It is a clever book. The book manages to cover the entire range of North American amphibian diversity without getting bogged down in taxonomy and classification. Instead, the taxonomy is treated intuitively (for want of a better word); it is implicit, and it is elegant. So, to begin with, the anurans (frogs and toads) and the caudates (salamanders and newts) are covered in separate sections named, simply, "Frogs of North America" and "Salamanders of North America." It took me a few moments to understand how the species were organized as there are no explicit written guidelines, and there are no blaring titles or subtitles. The families are treated alphabetically (subtly indicated by an inconspicuous footer at the bottom of each page), and then the genera are dealt with alphabetically within each family. Finally, the species are described alphabetically within each genus.

It is a useful book. The authors have taken great care to use up-to-date data on taxonomy and distribution, and the book is rich with resources including primary literature and web sites. It essentially combines the information from two previous reports to the Global Declining Amphibian Populations Task Force (Green 1997; Lannoo 2005). But instead of the usual blob maps seen in most field guides, they have used high-resolution plots on topographic maps, representing distribution data painstakingly gathered from a variety of reliable sources. This allows the reader to relate species distributions to topography in a way that is not possible in most blob maps. The maps also include simple political boundaries with the plots representing "centroids" of counties or equivalent. The only criticism I have of the species distribution maps is that because the dots are placed on "centroids" of various kinds, they are often shown more-or-less evenly spaced in an artificial-looking grid-like fashion making me think that perhaps a more "organic" shading (e.g., translucent yellow) might have been better (but then we would be back to the blob maps).

The book begins with an introduction to amphibians and their distribution, including an interesting map showing the relative densities of amphibian species in North America. For this the dot-plots are very effective. My one problem with this map is that it is so small, and some of the colors are so similar, that I had to use a magnifying glass to distinguish them. The authors include a special section at the end where they explain how the maps were made, and are careful to point out that the book covers only North America north of Mexico. But it deals with this part of North America as a whole continent, with a necessary and interesting northward-shifted perspective that emphasizes more of Canada than most Americans (i.e., U.S. citizens) are used to. I count this healthy shift of perspective as a useful aspect of the

book for understanding amphibian distribution, and no doubt reflects the fact that it is a collaborative effort between researchers from both Canada and the United States.

This is a wonderful book to have on your coffee table, as well as in your office or even in your backpack. It is a useful compendium of information on North American amphibians that manages to be esthetically pleasing as well.

e-mail: Ryan.Ellis@museum.wa.gov.au

Species belonging to the Children's python (*Antaresia*) and carpet python (*Morelia*) groups are among the most sought-after species in Australian herpetoculture and their popularity is growing rapidly in the international market. Their ease of care in captivity and ready availability (in Australia) makes them among the most desirable snakes to keep—comparable, for example, to Ball Pythons in the USA. In particular, the small size of *Antaresia* species (less than 1.8 m, and 60 cm or smaller in *A. perthensis*, the pygmy python), their ease of breeding, and overall adaptability to captivity, combined with a large variety of captive-bred morphs mean that these snakes have something for everyone.

Every now and again a book is published that becomes a "must have" highly valued reference for its target audience. For Australian python herpetoculture these have included *Pythons of the World. Volume 1, Australia* by Barker and Barker (1994), which remains one of the most comprehensive Australian python books, and the more recently published and herpetoculturally-focused *Keeping and Breeding Australian Pythons* edited by Mike Swan (2007). *The Complete Children's Python* and *The Complete Carpet Python* represent the next generation in this tradition. These two books are "must haves" for any *Antaresia* or *Morelia* keeper and breeder, or anyone with a general interest in pythons. The authors are well known Australian python breeders in the US (Justin Julander and Nick Mutton) and Australia (Peter Birch) and all have been enthusiasts from a young age. All three have extensive experience keeping and breeding various species from each group and have a wealth of experience and information to offer the reader. The effort and dedication expended by the authors is inspiring; just a few page flips and it is evident how much they have put into these books. The *Morelia* book has a foreword by Australian python and captive breeding expert John Weigel who states that the authors have "presented a well-researched and fascinating summary of just about everything that is presently known about carpet pythons." He couldn't be more correct, and the same applies for the *Antaresia* book.

Each book offers a smorgasbord of information for the species it discusses as well as a wealth of photos representing one of the best available image collections for the taxa treated. The books are produced using quality materials and will no doubt withstand years or decades of wear and tear. The data presented in the books are accurate for all species and give a good representation of existing knowledge. Spelling or grammatical errors are minor and infrequent.

Both books follow a similar format, although topics do not necessarily parallel one another exactly between the two. Section I of each book contains an introduction that gives a brief general overview of the book and the species discussed therein. In addition, the *Morelia* book has a small subsection in the introduction on Myths and Misconceptions. This is also where those not already confused by the "*Morelia spilota* complex" will be when they see that the authors have made some nomenclatural changes—recognizing some subspecies, but not others, as full species. While some of these changes may be warranted, no clear justification is presented. To confuse matters further, the Rough-scaled Python (*Morelia carinata*) is included in the *M. spilota* book, but other species of *Morelia* (e.g., *kinghorni, oenpelliensis, viridis*) are absent.

Section II (*Morelia*) or chapters 1 through 5 (*Antaresia*) present species accounts providing a natural history overview of the species including information on natural distribution, size, coloration, habitat and natural history, and reproduction. Each species profile is accompanied by many photographs displaying various natural habitats and morphs. Many herpetocultural publications are deficient when it comes to providing background information on behavior and natural history but these two books are an exception. The species profiles provide a wealth of background information that is useful when dealing with captive specimens. However, if you are pulling the book off the shelf and

planning to read a few or all of the species profiles at one sitting you may find the text a bit repetitive for a few profiles.

Of note is the section within the *Antaresia maculosa* species profile "Notes on the recently discovered population of *Antaresia* from New Guinea," which deals with the incredible discovery of an *Antaresia* species with affinities to *A. maculosa* from the Western Province of Papua New Guinea (O'Shea et al. 2004). This is the first record of the genus outside of Australia and provides further evidence of the historic connection between Australia and New Guinea.

Chapter 5—"Pygmy Banded Python *Antaresia* sp."—provides a profile of a suspected new species of *Antaresia*. The species profile does everything but formally describe this putative new species. While it may, in fact, be a new species there is no justification provided to support this and with the limited information presented there is no way to exclude the possibility that these specimens may be hybrids within a zone of sympatry of *A. maculosa* and *A. stimsoni*. Although a new species of *Antaresia* would be wonderful for Australian herpetology, I believe the chapter could have been omitted until such time as the issue has been resolved and more information available.

Following the species profiles are chapters on evolution and taxonomy—"The Evolutionary History of Carpet Pythons" (section III in the *Morelia* book) and "The Evolutionary and Taxonomic History of the Genus *Antaresia*" (Chapter 6 in the *Antaresia* book)—that discuss the origins of snakes, their evolutionary history, relationships within and between the focal genera, and taxonomic history (for *Antaresia*). The subject of evolutionary history can be complex for those new to the subject but the authors do an excellent job in breaking it down so that it is easily digested and the key points are retained. Treatment of the nomenclature is largely lacking in the *Morelia* book and would have been useful, especially in providing justification for the changes in taxonomic rank made by the authors.

Section IV—"Carpet Pythons in Captivity" in the *Morelia* book (chapters 7–9 in the *Antaresia* book)—cover all the key elements for the keeper or breeder, with extensive information provided on all aspects of captive husbandry, including housing, heating and humidity, feeding, and reproduction. Readers will find the sections on reproduction of particular interest; keepers seems to have different results and varying levels of success so it is always good to have detailed records and observations as the basis for comparison. Based on the sheer quantity of information on every page it is clear that the authors are in their element in this section.

All keepers hate to deal with diseases, disorders, and most of all, parasites. The section of each book covering these not-so-enjoyable aspects of the hobby provide great information to prevent, and if necessary, manage these issues. Many new keepers are easily panicked and often jump to conclusions, assuming a major problem when something out of the ordinary (but still normal) occurs. At the end of the day, if in doubt, get it checked out.

The final section of each book deals with morphs. It is one of the largest sections and profiles the natural and captive morphs of species of *Antaresia* and *Morelia* discussed in the book. New morphs will continue to be developed, but this section provides a brilliant display of the possibilities. Whether you are a beginner looking for your first snake or a dedicated breeder looking for ideas for the next big project, this section will be useful. It acts almost as a shopping list; one can only imagine the corresponding price tags. If anything, this section shows how productive the herpetocultural industry is and confirms that whether it be size, color, or pattern, these pythons have something for everyone.

The photos represented in these two volumes cover nearly all species and natural and captive variants and must be one of the most comprehensive published image collections of these pythons. The photos are by a diversity of photographers—a nice change to the monotony of nearly identical poses that can result when images are drawn from a single source. If one is not interested in reading these books, the photos alone will make a purchase worthwhile.

On the other hand, with a photo, or sometimes two, displayed on nearly every page, the reader is sometimes left wanting more text. The quality of some photos makes one wonder if all are really necessary. It is a little annoying to find photos that almost completely crowd out the text. For example, in *The Complete Children's Python*, p. 28 has 17 lines of text, each with a maximum of two words, whereas p. 42 has 35 lines text, none with more than three words, seven of which have been split across two lines.

Reading the book and admiring the numerous photos leads the reader to wonder: if these animals are not easily exported out of Australia, how have so many found their way to other countries. Illegal exportation or smuggling of reptiles is a well-known threat to reptiles across the world, especially in Australia. One could argue that good herpetoculture books can almost act as "smugglers' catalogues" providing a comprehensive summary of all of the amazing snakes that are available. Regardless of the ultimate origin of these reptiles, books like these highlight the impressive scale of captive breeding in the herpetocultural industry, particularly in the United States.

While they may not take pride of place on the bookshelves of naturalists or researchers, both books are essential for any keeper or prospective keeper of these species. Those who purchase pythons, especially beginner or intermediate keepers, will find the book an extremely valuable resource. For the more experienced keeper and breeder, the books will still be worth the purchase, if not for the information then for the vast collection of photos. Especially for the first time keeper, these books should be at the top of your priority list! Don't let the cost deter you, they are worth it.

Herpetological Review, 2014, 45(3), 531–534.
© 2014 by Society for the Study of Amphibians and Reptiles

When I was in grammar school, my parents moved to a small suburban town outside of Chicago. A few miles from our house, a beautiful pond and surrounding forest was my favorite haunt. Every few days, I would peddle my bicycle there, and spend hours watching wildlife, including a robust colony of Plains Garter Snakes (*Thamnophis radix*). One day to accommodate a new housing development, the pond was drained and the forest was being cut. A few weeks later, many snakes started showing up in my neighborhood, surprising since the area was highly urbanized. At first, I was delighted as my basement was already filled with living ophidians and these new snakes nicely complemented my collection until I realized that these creatures were driven from their living space, never to return.

A year or so later, I visited the Art Institute in Chicago and saw a large oil painting by Peter Blume called "The Rock." The image was so striking, I was unable to turn away for many minutes; the painting is not about death to humanity, but to nature, and the trouble we continue to have coexisting with it. At that moment, everything became clear—I was watching the planet being dismantled by humans and replaced with far less interesting manmade creations. Even more troubling, the pace was accelerating. I trace this moment to the exact time in my young life when I became a committed environmentalist.

Books by Current or Former Zoo Workers

Sean Foley has worked for over twenty years in the herpetology department at Riverbanks Zoo and Garden in Columbia, South Carolina. He has written a rip-roaring adventure yarn involving Jamaican iguanas, pirates, lost treasure, the island of Jamaica, a lonely thirteen-year-old girl, and friendships. Pick up a copy for a pleasurable read (*The Iguana's Eyes*, 2013, Columbia Vista Publishing, 301 pp., ISBN 978-0-9899618-0-6). It was refreshing to read a novel that accurately described herps without embellishment or sensationalism and it was certainly unusual to read his plea at the end for Jamaican Iguana conservation. The species was described by John Edward Gray as Colley's Cyclura (*Cyclura collei*) in 1845. The taxon was exceedingly rare in 1916, mentioned in the account by Thomas Barbour and G. K. Noble (A revision of the lizards of the genus *Cyclura*. Bull. Mus. Comp. Zool. Harvard 60[4]:139–164), and was found on a few small islets off the coast of Jamaica where the predaceous mongoose had not been introduced. The lizard was later thought to be extinct. In 1970, a hunter's dog discovered a carcass and a survey later found about 100 lizards left in the wild in the Hellshire Hills. In 1993, Allison Alberts called it the most endangered lizard in the world (Vivarium 5[1]:12–14, 30).

Jeffrey M. Lemm and Allison C. Alberts from San Diego Zoo Global in California have worked for many years with iguanid lizards of the genus *Cyclura*. Their comprehensive book—*Cyclura: Natural History, Husbandry, and Conservation of West Indian Rock Iguanas* (2012, Academic Press, London, San Diego, 221 pp., ISBN: 978-1-43-773516-1)—with contributions from four additional authors, includes chapters on evolution and biogeography, species accounts, natural history, husbandry, nutrition, health and medical management, and conservation. What was indeed hopeful is their description of the successful head-starting program for the Jamaican Iguana at the Hope Zoo in Kingston but one should not be too confident as there exist today sizeable threats to irrevocably alter the Hellshire Hills for human purposes, the only place where the lizard is found. Their future assessment: "Despite the fact that most rock iguana populations have suffered serious declines, there is reason to be optimistic about their future. The IUCN's 1997 decision to sanction the formation of a West Indian Specialist Group (since expanded to become global Iguana Specialist Group) was instrumental in bringing together experts internationally throughout the region to develop a coordinated plan for the long-term conservation of West Indian iguanas." The San Diego Zoo has been an integral player over many years leading this effort; as an example, Tandora Grant has been tireless in her efforts to bring attention to the plight of the Jamaican Iguana.

The Invisible Ark: In Defense of Captivity, by David M. Barker and Tracy M. Barker, was published in 2014 (Vida Preciosa International, Boerne, Texas, 169 pp. ISBN 13:978-0-9785411-1-8). The title explains its contents and is an important primer for those who must defend their interest in maintaining captive amphibians and reptiles. They also cover the important contributions generated from the private sector and suggest ways that this community can contribute to conservation efforts. There is an extensive narrative on the history and challenges of invasive herpetofauna, especially the Burmese Python and other large constrictors in the southeastern United States. Many of their papers on this topic have been published in the *Bulletin of the Chicago Herpetological Society*. Years ago, David and I worked together at Dallas Zoo and Tracy spent time at the National Zoological Park in Washington, DC.

A rarity indeed is any privately-owned herpetological exhibit that survives for a decade or more but one lasting over 50

years is awe-inspiring. The mortality rate for such enterprises is staggering so the book written by Clyde Peeling, *Reptiland; How a Boyhood Dream Became a Modern Zoo* (2014, Peeling Productions, Allentown, Pennsylvania, 132 pp. ISBN 978-0-9960790-0-6), is amazing. This is not a typical private exhibit for it is accredited by the Association of Zoos and Aquariums (AZA), which insists on high standards for accreditation by its members. I have followed Peeling's career for years and his stories about our friends and colleagues certainly resonates with me, although his inscription to me in his book was a bit startling: "To Jim, We may be the last two standing! Your friend, Clyde."

Zoos and Aquariums: What is Next?

Reptile keeping has developed into a science during the past two decades, and the advancements, especially in the fields of medication and captive breeding, are little short of phenomenal. Compared with the sophisticated techniques that are now available, our efforts of half a century ago seem crude in the extreme. In those days we often considered ourselves lucky if a majority of our animals lived a year or two, and what little captive breeding occurred was fortuitous, not planned.

Roger Conant (1980)

Thus captivity will result in intensive selection, molding the animal in a manner quite different from that followed in its natural environment. The final product will be an animal much better adapted to live in close association with humans, in the home or laboratory, but less well adapted for life under natural conditions.

Henry S. Fitch (1980)

Captive breeding isn't designed to save species. It's designed to make humans feel better about ourselves. It's proof that whatever horrors we're wreaking on our planet, we're still willing to make Herculean efforts to save the animals most obviously suffering the consequences. But to effectively assuage our guilt, we need to see results—and truly successful captive breeding programmes, the ones that produce large numbers of wild animals which stay out of humans' way, rarely give us those. Instead, we latch on to the adorable and conscience-soothing spectacle of captive breeding itself. We're riveted by the Panda Cam, we turn up in droves to watch ultralight aircraft lead whooping cranes on their first migration. Puppet-rearing takes our love of captive breeding to the extreme by satisfying two guilt-absolving fantasies at once: it lets us play at being nature's saviour while also symbolically erasing human beings from the face of the Earth.

Reared by puppets. To breed condors in captivity, we must pull on the strings of nature. But does that matter if we save a species?

Lizzie Wade, *Aeon Magazine* (2014)

There are enormous challenges and changes taking place in our profession. Unsettling and penetrating questions are being asked about the value of what we do as zoo and aquarium professionals, both inside and outside our institutions, as evident in the quotes above. This column will discuss preparing for a changing world by using a new book, broad in scope, that addresses this fluid landscape. This book is *Zookeeping. An Introduction to the Science and Technology*, edited by Mark D. Irwin, John B. Stoner, and Aaron M. Cobaugh (2013. University of Chicago Press, Chicago, Illinois. 674 pp., ISBN-13: 978-0-226-92531-8 [cloth]; ISBN-13: 978-0-226-92532-5 [e-book]). In addition to positioning oneself for the future, many of the subjects covered in the 66 chapters, written by luminaries in the field, can be consulted for preparing protocols now required in our institutions; it is an enormously time-saving reference.

I wish to make several points here as to why this book is important. It is no longer possible to restrict one's zoo career to just keeping animals. Sometimes during job interviews, candidates have said that they prefer working with animals rather than humans—their applications immediately go to the bottom of the pile. If one wishes to move up the food chain and compete for higher jobs, then familiarity with administration, fundraising, supervision, public outreach, and other non-animal skillsets is critical. It is almost certain that the ability to read a budget spreadsheet is as important as knowing what current scientific name should be used for any taxon. One example here should suffice. I receive job descriptions from many zoos soliciting applicants to apply for positions beyond the keeper level and virtually all require a minimum of at least one year's supervisory experience and broad familiarity with the needs of zoos and aquariums. The tragedy is that most zoos do not offer learning opportunities to keepers so that these minimal requirements can be met.

We are not preparing the younger generation to be successful as potential curators. This is obvious when a position description is circulated throughout our membership and applicants begin to send résumés. Academics from the research side often have virtually no experience with a variety of living captive animals, public outreach, or personnel management. Some zoo workers who came up through the ranks have little experience in setting up successful research programs, either in the zoo or in the field, which often includes collaborations with those outside the zoo setting. It is striking that many applicants are unfamiliar with the rich history of the zoo and aquarium world, so one fears that

This new book, "*Zookeeping. An Introduction to the Science and Technology*," will certainly become the reference "bible" for the zoo and aquarium professional.

they may well repeat the mistakes made by their predecessors. Curators with a blend of these critical skills are hard to find now, at least this is what I am told by those entrusted with finding suitable candidates.

Our profession is becoming increasingly bureaucratic and much time is spent filling out surveys, answering an enormous number of e-mails, attending unproductive meetings, and preparing a plethora of memos in response to various issues such as visitor safety, personnel problems, and animal welfare. As a result, the time available to focus on biology is shrinking—this is a chronic complaint by my fellow zoo workers and I understand their frustration. I suggest that institutional representatives review all policies, jettison those which no longer apply, refine those that need improvement and keep only those that are proven to be effective and useful.

Zoo administrators now must deal with the internet, such that any incident (animal escape, visitor injury, or untimely animal death) can be instantly communicated worldwide and can affect the zoo's reputation. Some people dislike zoos and aquariums, accuse us of ignoring animal welfare, and do not understand the value of zoo programs to conservation in the broad sense. We may have inadvertently contributed to this perception by personalizing individual animals. Perhaps it seems safer and easier for us to focus on individual animals: we often use pet names for them, try to enrich their lives by interactive play and using manmade objects, and bond with them as if they were surrogate humans without concern for imprinting or other side effects. When animals are near the end, they cannot send us a note saying "Do Not Resuscitate." But we employ dramatic medical interventions and costly procedures to ensure that they live to a ripe old age, and mourn and grieve over their deaths (in a few extreme cases, grief counselors have consoled the animal care staff for an animal death and quasi-memorial services have been held). In sum, we demonstrate that we care and we publicize to our audiences that we do.

Enrichment has become one of the newest trends in the zoo world, but I am not certain how we measure whether our changes to an animal's living space and activities actually improves their lives or whether it just makes us feel better. I do know that if we were keeping animals successfully by fulfilling all of their needs, we might no longer need to resort to techniques like assisted reproduction, cryopreservation of gametes, and hand-rearing. We do not spend enough time trying to understand and convey the need to protect an entire species or larger clade rather than individual animals—confronting and explaining to our visitors thorny issues like the need for euthanasia to deal with limited space in zoos, the issues confronting wild populations, climate change, the sixth mass extinction event, and advent of the Anthropocene—and how our captive colonies should be managed more effectively to accomplish conservation goals.

Many of our zoos are experiencing severe financial shrinkage and the future for some may be problematic. Fundraising, development, and public relations have become an integral part of the zoo scene. Some of my herpetological colleagues complain that their time is spent leading tours, giving public presentations, and interacting with potential benefactors rather than working with the collections. These colleagues have an incredibly short-sighted view; in fact, their programs will disappear if there are no monies to support these initiatives.

Obtaining animals has become much more difficult. Moving animals between zoos and aquariums for our captive management programs has become more time-consuming, due to risk of infectious diseases, lack of quarantine space, and increased paperwork. There are few animal dealers now so zoos may be restricted to mounting their own collecting trips to range countries; these are limited, however, by travel and other expenses, increased paperwork for permits, and lack of reliable in-country associates. Even if these impediments are overcome, there are no guarantees that the animals will be found. While some zoos cooperate with hunting ranches for space to ensure genetic diversity for some large mammals, there is no such program for reptiles. Although an idea like this would have been inconceivable to me a short time ago, I can now envisage a day in the future where zoos could be forced to work more closely with hide dealers producing propagules to maintain large reptiles such as crocodilians, iguanids, varanids, boas, and pythons. Public outcry is certain to be deafening in the herp community, and administrators may need to be ready to defend this practice. As a herpetologist, I find killing any herp abhorrent (unless it goes to a museum collection), especially when their skins are being used in the fashion industry, but we are running out of time and space—and some protected wild populations are shrinking precipitously due to human exploitation. My sense is that convincing people to avoid purchasing animal products to drape on their bodies does not seem to be working effectively over the past decades—I still see plenty of snakeskin belts, handbags, and wallets, as well as shoes made from crocodile skins at the local department store and I suspect that most are collected from the wild. The IUCN Python Conservation Partnership is in favor of commercial python farming to combat the illegal trade for python skins (Natusch and Lyons 2014). For nearly eighty years, the Reticulated Python (*Malayopython reticulatus*) and the Burmese Python (*Python bivittatus*) have been harvested from the wild in Southeast Asia. An astounding nearly 500,000 skins are shipped on the black market every year for use in European fashion, worth an estimated one billion US dollars. This paper evaluates the economic feasibility and viability of captive breeding as a possible way to sustain and conserve them. One possible part of a future plan: do not harvest animals sent by zoos, but only their progeny not needed for sustaining captive populations.

The total of these onslaughts and new expectations is that our community has become defensive and tentative. For example, I have heard few discussions about management euthanasia for my entire career (45+ years) and the topic continues to be discussed rarely because there is great risk involved to those having the courage to act. In the past, zoo directors have lost their jobs over the controversy that erupted when they culled healthy animals that were not contributing to breeding programs. While the Copenhagen Zoo furor—after euthanizing a giraffe and four lion cubs for management purposes—has spurred a useful discussion of the issues among many zoo workers, virtually all of my non-biologist friends have roundly condemned this action. When I try to explain the rationale for doing this, they are unconvinced.

Finally, there is a conundrum. Some administrators, educators, graphics designers, and marketing people insist that the zoo visit must be a pleasant experience, not depressing or disconcerting. Our messages need to be simple, positive, and uplifting. Others maintain that the experience should be unsettling, because the natural world is disappearing at an unprecedented rate and humans need to be aware that their lives will most certainly change by living in an increasingly homogenized natural world. Zoo people have struggled with this

dichotomy for decades. My belief is that visitors are capable of connected thought so we need to address difficult concepts and challenges in a forthright way with our messages, but we also should cater to those who simply want to have a good day out.

So what is likely to happen to those older zoo workers who yearn for the good old days where life in a zoo or aquarium was far less complex? The answer is simple—the world is changing at a frantic pace, biodiversity is quickly leaving us, and those old days will never return. Get over it. But carefully reading this comprehensive new book by Irwin et al. will serve to identify the issues. Further, it shows growth, sophistication, and improvement in many of the things we currently do. Future challenges have been identified which must be addressed to ensure the survival of zoos, which in itself is a good thing.

Studies on Pythons, Boas and Anacondas, Dwarf Boas, and Round Island Splitjaw Snakes in Zoos and Aquariums

To most people constricting seems one of the most lurid and unpardonable things that snakes do, and through the centuries the habit has evoked a great deal of morbid lore. For example, though I come from an enlightened family, I grew up thinking that a constricting snake snatches up its prey, throws on coils and with chiropractic precision pulverizes each separate bone in its victim's body, licks the pulped prey all over to lubricate it, zestfully engulfs it and then lays up somewhere for a year or more, stupefied by its excesses.

Archie Carr, *The Reptiles*, 1963

Introduction

This wonderful quote by Archie Carr sums up the responses by zoo visitors when they flock around an exhibit to watch a feeding snake, especially a large constrictor. Screams of disgust, amazement, and disbelief are heard ringing through the public area as the prey gradually disappears from view. But in spite of the outcry, virtually no one leaves the building until dinner is finished. They are certainly unsettled when they discover that some reptiles—crocodilians, Komodo Dragons, large constrictors—can kill and eat people so the look of horror on their collective faces is arresting and dramatic. Part of the response is that no one wishes to be eaten of course, but their collective response also suggests to be dispatched by an animal so far down the phylogenetic tree is unacceptable, almost embarrassing.

In this paper, I show the history of keeping boas and pythons in zoos and aquariums by using early images of many genera and include some personal anecdotes. To avoid repeating myself, I suggest that the reader consult my earlier papers in *Herpetological Review* on venomous reptiles (Murphy 2014). Many of the descriptions of their maintenance, husbandry, behavior, and challenges facing captive managers and conservation biologists in the zoo world also apply here to non-venomous taxa.

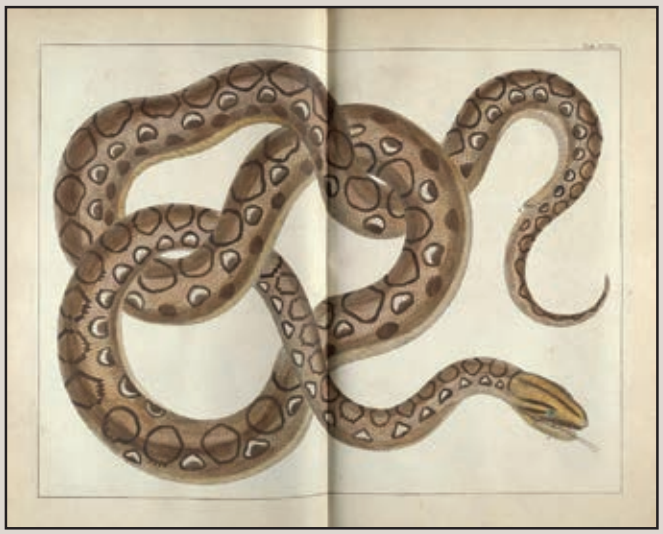
To avoid confusion, I am incorporating the original technical names used by the authors in their publications. To update these names, consult McDiarmid et al. (1999), Reynolds et al. (2013), Kaiser et al. (2013), Pyron et al. (2013), and Uetz and Hošek (2013).

Review of the Literature

With regards to large constricting snakes, several notable books should be recognized. An important book by Zdenek Vogel, briefly working for the Prague Zoo, was the major reference book in Europe in 1964: *Reptiles and Amphibians. Their Care and Behaviour*. Frederick William FitzSimons, Director of the Port Elizabeth Museum and Snake Park in South Africa, published *Pythons and Their Ways* (1930). During part of his career at Ft. Worth Zoo in the mid-1960s, John Mehrtens began compiling information and photographs for a large book called *Living Snakes of the World in Color*, published in 1987. In 1999, Eugène Bruins from Natura Artis Magistra in Amsterdam, provided extensive coverage of insects, arachnids, amphibians, and reptiles in his book *Encyclopedia of Terrarium*. Another example is the comprehensive book by John Weigel from the Australian Snake Park, *Care of Australian Reptiles in Captivity* (1992). Richard A. Sajdak, retired herpetological curator at Milwaukee County Zoo in Wisconsin, covered boas and pythons in his book *Hunters in the Trees: A Natural History of Arboreal*

Snakes. Peter Brazaitis from Bronx Zoo wrote a lovely book called *You Belong in a Zoo. Tales of a Lifetime Spent with Cobras, Crocs, and Other Creatures,* detailing his life as a lowly paid reptile and amphibian caretaker, starting in 1954. Brazaitis' book includes one particularly interesting story involving the theft of an African Rock Python (*Python sebae*) and other reptiles at night by three young boys who scaled the roof and climbed into the Reptile House on several occasions to pick through the collection in order to build their private zoo. The python proved to be aggressive, chasing one of them around his dwelling. Keeping that snake fed was another challenge because rats were expensive and the snake had a prodigious appetite—the thieves carried the nasty ophidian back to the Zoo and returned it to its cage. Some baby Boa Constrictors were stolen as well but one boy's grandmother did not like snakes and flushed them down the toilet. Another large boa escaped and was killed by a city bus on a busy street in the Bronx.

There are several important tomes by non-zoo herpetologists. Clifford H. Pope wrote *The Giant Snakes; the Natural History of the Boa Constrictor, the Anaconda, and the Largest Pythons, Including Comparative Facts about other Snakes and Basic Information on Reptiles in General*. Sherman A. Minton, Jr. and Madge Rutherford Minton compiled a book focusing on the big five constrictors and their relatives*: Giant Reptiles*. Their book also covered other large reptiles, helpful as a reference source. Richard Shine has studied many Australian pythons in the field, especially the Water Python *Liasis fuscus*. His book, *Australian Snakes: A Natural History*, described the first detailed study of a python—habitat, density, diet, growth rate, and reproductive biology. Brian Kend accumulated observations and provided photographs in his book, *Pythons of Australia*. A comprehensive book covering size, food and feeding, sex, attacks on humans, exploitation, and conservation was written by John C. Murphy and Robert W. Henderson—*Tales of Giant Snakes: A Historical Natural History of Anacondas and Pythons*. Harry Greene has written an insightful book—*Snakes: The Evolution of Mystery in Nature,* which includes information on classification and general biology. Two beautifully illustrated volumes on Australian Pythons and Ball Pythons were written by David G. Barker and Tracy M. Barker in the series *Pythons of the World* (1994, 2006). Barker et al. (2012) have been researching and correcting published lengths of giant pythons and other large constrictors. They also published information and species descriptions in *Grzimek's Animal Life Encyclopedia* (Hutchins et al. 2003). An excellent book, edited by Robert W. Henderson and Robert Powell and entitled *Biology of the Boas and Pythons,* should be in every herpetologist's library. Harvey Lillywhite has recently published a book that covers physiology of snakes, *How Snakes Work: Structure, Function and Behavior of the World's Snakes* (2014). This is an important reference book for zoo workers, especially helpful when preparing graphics focusing on the intricacies of physiological ecology. One unique feature of this book is the inclusion of Lillywhite's extensive field research.



There are several important journals in Europe. Beginning in 1958, the journal *Akvárium terárium* (*Praha*), is now published monthly. This publication features articles on captive maintenance. Another journal, *Živa* (*Praha*), also focuses on papers dealing with herpetoculture. The Prague Zoo (Zoologicka Zahrada Praha) is located in the Czech Republic and supervisor Ivan Rehák has published many papers in both outlets, based on the collection of boas and pythons at the Zoo. Beginning in 1990 (Volume 2), the journal *Scientific Research in Zoological Parks, Moscow* has been an important venue for the staff at the Zoo, and they have published many papers on captive reptiles and amphibians, mostly based on observations of behavior and/or reproduction at that institution. These include studies on various Asian and Asian-Pacific pythons (Odinchenko 1992; Vassiliev and Balakina 2000).

There are papers on medical management: Susan Barnard from Zoo Atlanta and her associates have published a number of papers and books on parasitism and husbandry in boas and pythons (Barnard 1996, 2000; Barnard and Upton 1964–). Camin and associates (1948, 1953, 1964) documented the ravages caused by the snake mite (*Ophionyssus natricis*) in captive reptile collections and boid snakes seem to be particularly plagued by these parasites. Wright (1992) addressed dysecdysis in boid snakes with neurologic diseases. "Mouth rot" (Infectious or Ulcerative Stomatitis) seems to be a disease to which boid snakes are particularly prone. One of the most insidious diseases to infect boas and pythons is Inclusion Body Disease (IBD). It is beyond the scope of this paper to go into a lengthy discussion concerning clinical signs, laboratory diagnosis, route of transmission, and prognosis and treatment but two points must be stressed—snakes showing clinical signs of IBD should be euthanized and strict quarantine should be at least 4–6 months (Mas 2008) and 8 months is recommended by other authors. Consider the negative ramifications for the timely movement of snakes in the families Boidae and Pythonidae—between institutions involved in AZA Species Survival Plans—when quarantine times must be dramatically expanded. I asked pathologist Elliott Jacobson what a reasonable length of time would be to quarantine snakes. He said that as long as possible would be a good plan but cost and practicality should be considered. A 90-day period should be the absolute minimum. For additional information, consult Schumacher et al. (1994) and Chang and Jacobson (2010).

From Melbourne Zoo, Banks (1985) observed feeding and sloughing in a collection of captive snakes, including pythons. Using data from a number of zoos, Greene (1983) strengthened his analysis of the dietary correlates of the origin and radiation of boid snakes. Barton and Allen (1961) recorded feeding, shedding, and growth rates of captive boid snakes at the Highland Park Zoological Gardens in Pittsburgh, Pennsylvania.

Richard Ross created the Institute for Herpetological Research in Stanford, California. His organization worked closely with multiple zoos and published many papers on python and boa reproduction, such as his overview of captive pythons in the SSAR book *Reproductive Biology and Diseases of Captive Reptiles* in 1980. Three signature books were published (the last two with Gerald Marzec) by the Institute: *The Python Breeding Manual* in 1978, *The Bacterial Diseases of Reptiles: Their Epidemiology, Control, Diagnosis and Treatment* in 1984, and *The Reproductive Husbandry of Pythons and Boas* in 1990. The late Thomas Huff from the Reptile Breeding Foundation in Picton, Ontario (1979) was a long-term associate of the Institute and specialized in breeding programs for insular boas of the genus *Epicrates*. The only species now in *Epicrates* is the *cenchria*-complex—all other insular boas are now classified in *Chilabothrus*. He worked with *Chilabothrus*.

Retired Smithsonian National Zoological Park curator Dale Marcellini published two papers on the proper requirements to incorporate when building zoo herpetological collections (1981, 1994). In the first paper, called "Boring is Beautiful," he stressed the need to develop a species selection plan based on exhibit potential, hardiness, longevity, educational value, breeding

FIG. 1. According to a study on attractiveness of snakes according to human perception, the Brazilian Rainbow Boa (*Epicrates cenchria*) was the winner. Illustration from Albertus Seba, 1734–1765, *Locupletissimi rerum naturalium thesauri.*

potential, availability, and program investment in other zoos. There seems to be another element driving the choices of taxa to be included in our collections which had never occurred to me but surfaced when I read an intriguing paper in 2008 by Jana Marešová and Daniel Frynta: "Noah's Ark is full of common species attractive to humans: The case of boid snakes in zoos." Their abstract reads: "As the fate of endangered species may largely depend on human decisions, we analyzed the effect of species attractiveness to humans on conservation efforts devoted to captive breeding. Our respondents were asked to rank photographs of 56 species of boas and pythons according to perceived attractiveness. Surprisingly, attractiveness, body size and, marginally, also taxonomic uniqueness of the species were the only significant predictors of the size of zoo population. On the other hand, variables putatively associated with species rarity (inclusion in the Red List or protection by international law, geographic range size, and commercial price) had no effect. The range size was, however, positively correlated with attractiveness. As the perceived attractiveness affects at least some components of the conservation effort, it should not be further neglected but should be routinely included into conservation reasoning." The common Brazilian Rainbow Boa was champion of attractiveness (Fig. 1) whereas the poor graceless endangered Puerto Rican Boa was nearly at the bottom.

Here, I must assure the reader that I do not spend waking hours sniffing snake cloacal glands but when one works with a large living collection, the opportunity to be sprayed with musk is ever-present. It is well known that many natricines exude unpleasant musk. Even more pungent is that from some of the larger insular *Chilabothrus*: Jamaican Boa (*C. subflavus*), Cuban Boa (*C. angulifer),* Haitian Boa (*C. s. striatus*), and Bimini Boa (*C. s. fosteri).* In my view, the clear winner is the Oaxacan Dwarf Boa (*Exiliboa placata*)—this diminutive snake expresses the most foul-smelling and nauseating musk imaginable. It was so penetrating that the odor lasted for days on my clothes and remained on my hands, even after repeated hand-washings. I asked Jon Campbell, who had collected the snakes (see Campbell and Camarillo 1992) why the smell was so disgusting and amount so copious. He felt it was an anti-predator mechanism because of the plentiful predators (e.g., weasels [*Mustela frenata tropicalis*?] and various species of opossum [e.g., *Philander* and *Didelphis*]). Weldon and Thomas (1995) and Wood et al. (1995) published a comparative analysis of proteins in the scent gland secretions of snakes, using boas and pythons from many zoos.

History

Liliane Bodson (2003) wrote a fascinating account of the capture of an African Rock Python in the third century B.C. for King Ptolemy II Philadelphus's (reign 282–246 B.C.) collection of exotic or rare animals; this snake was carried from the capture site in a large woven basket constructed of rush and presented to the king in Alexandria. The snake was caught in the present day location covered by most of Sudan and the northern part of modern Ethiopia—"Consequently, when it retreated to its accustomed lair, they closed in upon it, but only so far as not to arouse it still more. And when it came near the opening which had been stopped up, the whole throng, acting together, raised a mighty din with their arms and thus increased its confusion and fear because of the crowds which put in their appearance and of the trumpets. But the beast could not find the opening and so, terrified at the advance of the hunters, fled for refuge into the mouth of the net which had been prepared near by." The actual size of the snake was said to be 13 m which is unlikely but it must have been large. What is amazing is that it was transported overland and by boat, a distance of roughly 2000 km in a straight line if the starting point was modern Khartoum. Herpetologists know that snake sizes are often exaggerated but if the snake was between 19–21 feet (5.7–6.4 m) (or more) in total length, it could weigh a hefty two hundred pounds or more—also remarkable is that it survived the journey, arrived at the zoo in decent shape, eventually fed and became habituated to captivity. A snake that size would not need to be fed during the trip but dehydration would have been a major concern.

Centuries later, Georg Seger (= Segerus in Latin) in Germany (1629–1678) published the first observations on captive snakes (see Daszkiewicz 2001 for his biography). He recorded shedding and egg-laying in "Aesculapian snakes" but it is unclear whether the species described was the ratsnake (*Elaphe longissima*) or the grass snake (*Natrix natrix*). He removed their tongues initially as this organ was thought to inflict mortal wounds, but this procedure did not contribute to a long life in captivity so the practice was discontinued. Seger helped one of his snakes during egg-laying and attributed her success in laying thirteen eggs to his help. In another case, he helped his snake during shedding by holding its skin.

"The reptile house [London Zoo] also catered to a public appetite for menagerie theatre, and the Friday evening feeding sessions when the snakes were fed with live prey were reported to be spectacular events. It was the ability of the boids to kill their victims through processes of constriction, asphyxiation, and deglutition that particularly riveted audiences, igniting a debate that smoldered in the national press from the late 1860s to the turn of the century concerning the extent to which such sights were appropriate for children, and whether the feeding of live animals was in keeping with natural law or just a morbid, sadistic entertainment" (Smith 2005). The feeding of live food to snakes was an issue so inflammatory in London over a century ago that it was discussed in Parliament. A few dramatic quotes from Blunt (1976) should put the controversy in proper perspective: ". . . that a rabbit should be shut up in a cage with

a snake without any chance of his life, deprived of the means of escape allotted to him by nature, and subject to the exquisite torture of terror prolonged by factitious circumstances and enhanced by despair" or ". . . trembling rabbits devoured by a serpent?—a monster reptile maintained and thus feasted for the pleasure of the English—for their children . . ."

In 1882, Catherine G. Hopley published an interesting book called *Snakes: Curiosities and Wonders of Serpent Life*. In Chapter XII called "Ophidian Acrobats: Construction and Constriction," she wrote ". . . So did some young boa constrictors, born alive at the Gardens, June 30th 1877. They were from fifteen to twenty inches in length, and had teeth sufficiently developed to draw blood from Holland's hand, showing fight and ingratitude at the same time. They were exceedingly active, and fed on young mice, which they constricted instinctively. One of them, known as 'Totsey,' subsequently *hung* for her portrait on page 201." Holland was the reptile keeper at London Zoo. The portrait, a line drawing, depicts Totsey coming down from an overhead branch to constrict one of three live sparrows on the floor. In Chapter XXIV, "Do Snakes Incubate Their Eggs?," Hopley provides data and information on the snakes at the London Zoo: getting over 100 eggs ('more than a bushel') from a python in 1862, breeding five 'seven-banded snakes' (*Tropidonotus leberis*) [now *Regina septemvittata*] in August 1872, breeding seven *Coluber* [= *Natrix*] *natrix*) in June 1873, 14 (of which 10 survived) yellow Jamaican boas (*Chilobothrus inornatus*) which crawled to the top of their cage in August 1873, and 20 young from a Panamanian boa constrictor in July 1877, ". . . which displayed ability to take care of themselves forthwith by leaving the marks of their teeth on Holland's fingers."

Watching large constrictors feed is always an exciting time for zoo patrons. In early days, feeding captives, especially large constrictors, was dramatic, indicated by four early accounts. Reverend Gregory Bateman in *The Vivarium* (1897): "No animals, in their manner of taking food, are more capricious than Snakes. Sometimes their desire to feed is so great, that they will eat a meal out of all proportion to their size; and, sometimes, without any apparent cause, they will refuse food, even the most suitable, until they die of starvation. As a rule, these creatures cannot be persuaded to seize any prey but that which is natural to them. For example, a Snake which lives upon frogs will not on any account, as a general thing, take lizards, though the latter might be just as nourishing to the Ophidian as the former, and possibly even more so, nor will a lizard-eating Snake be tempted to swallow a newt."

"Even if Snakes did never refuse their natural food, the supplying of it is not always convenient, nor is it, to most people, pleasant. Young mice and rats, frogs and lizards are not continually at hand, and it is not, by any means, an attractive sight to see a Snake, at evident discomfort to itself, swallowing a live animal or one recently constricted or poisoned." In support of the practice of assisting snakes to feed artificially, Bateman continues . . . "I believe many keepers of reptiles in Zoological Gardens adopt, to a greater or lesser extent, the artificial system of feeding their charges. The largest Snake in the Reptile House, Regent's Park, London, and which is also perhaps the largest Snake in captivity anywhere, has been fed by hand for the last three years at least, and is in splendid condition, weighing probably something like 18 st. This Snake, the Reticulated Python (*Python reticulatus*), receives its food regularly once a week . . . There are several methods of administering food to Snakes. For example 1) some Snakes will swallow a dead animal, or even a piece of meat, when it has been simply placed between their jaws. 2) The Snake's mouth is forcibly opened, and a dead small animal, dipped in milk, is pushed down the throat, and then worked down the gullet by the manipulation of the fingers outside the Snake's body. 3) Pieces of meat, or portions of animals, dipped in milk, are pushed sufficiently far down the opened mouth of a Snake by means of a smooth stick. 4) A tube is filled with suitable food, and passed down the gullet of the reptile, and then the contents of the tube are discharged by means of a piece of cane used as a ramrod." In London at this time, boas and pythons were being sold: Diamond Pythons—between 10 shillings and £3.00 (75 cents to $4.50); African Pythons approximately 4 feet long—25 shillings ($1.88) to £3.00 ($4.50); Ball Pythons—same price as other "pythons;" Anacondas—£30.00 ($45.00).

FIG. 2. A well-dressed Raymond L. Ditmars (right) thrusting a rabbit into the gullet of a Reticulated Python at Bronx Zoo (New York Zoological Park) on 9 April 1913. Some zoos at this time force-fed large constrictors for visitors and in some cases, patrons could pay a fee to hold the snake during feeding. Courtesy of Wildlife Conservation Society headquartered at Bronx Zoo, provided by John Behler.

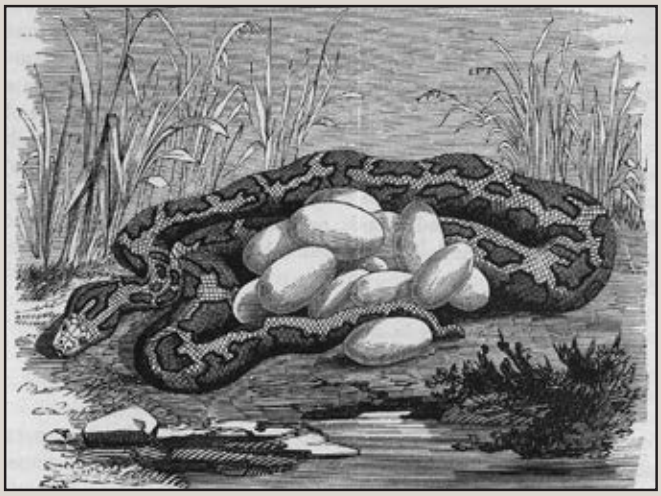
There is a famous story about Raymond L. Ditmars and his keepers (Fig. 2) by A. W. Rolker in the book *The Story of the Snake* (1956): "A most famous instance of snake feeding happened a year ago in the New York Zoölogical Park when Czarina, a twenty-foot regal python, one of the largest specimens in captivity and known all over among naturalists, was fed against her will . . . For more than six weeks Czarina had not touched food, when Curator R. L. Ditmars, in charge of the reptile house, decided to capture the monster, to take her out of her cage, to stretch her to full length, and to force food down her throat . . . Every keeper in every department of the Park was notified to report to the reptile house that evening, and the snake meal was prepared. Thirty pounds of rabbits were killed, bound together with twine, and fastened to a bamboo pole ten feet long . . . That evening when the visitors had gone the fight began—twelve men against the snake . . .Through a slot in the big door at the back of the cage the Curator peered to locate the snake. Then he threw open the door . . . Then the Curator, only a burlap bag in hand and trusting the eleven to follow, threw himself toward the monster and in an instant the bag was over her head. Blinded and with the hands of a man clutching her throat, like a giant spring hurled herself loose among the struggling men who had piled into the cage and were trying to clutch the wonderful coils. Through the cloud of dust within appeared glimpses of the fighting keepers and flashes of the lashing body, while the scuffle of feet and cries of the men sounded over all. The Curator, still clutching the throat of his

great adversary, staggered about, whipped back and forth like a jackstraw. Grabbing, groping, hugging, and tugging, the others were tossed like chaff here and there only to fall back to their work which now had grown a matter of life and death, for to release the snake and permit all hands to escape in safety would now have been impossible. Through the dust were seen five or six men lying side by side on their bellies trying to pin the snake to earth, but the next instant they were up in the air, tossed by the dreadful spring of those giant coils . . . But even Czarina's tremendous strength was unable to withstand indefinitely the assault of the small army of hardened and trained animal men . . . At the end of another five minutes they had pinned down the snake . . . Mr. Ditmars, still clutching the wicked head, was the first to stagger out of the cage. One by one the others followed, each lugging a share of the snake. The python was stretched full length on the floor of the house. The custody of the head was turned over to an assistant, and the Curator prepared to administer the food. The great jaws were forced apart, and the bamboo pole with its bologna of rabbits was shoved into the mouth and down the endless throat. . . . Still, as if lifeless, she remained, while down, down went the food, until, when nearly the entire pole was buried within the reptile, the rabbits were wriggled loose, and the great snake had been forced to feed."

Curator Edward Boulenger from London Zoo offered this explanation of the challenges of inducing a Reticulated Python to feed in 1914: "It is a savage snake, and usually untamable, but does exceedingly well in captivity; although somewhat capricious in the choice of its food, most specimens feed with some regularity. As an example of its capricious appetite, I would relate the curious story told of a specimen which lived some years ago in the Menagerie of the Jardin des Plantes. The snake in question, a very large one, had been starving for some months, although it had been offered kids, rabbits, guinea pigs, and various fowls, when a goose, which formed part of the collection and which had injured its leg, was put into the cage. The snake at once seized hold of it, and thus made its first meal since its arrival in Paris. It was naturally thought that, having lost its sulkiness, it would henceforth go on feeding. Not so, however; the ordinary bill of fare of captive Pythons was persistently refused, until, as an experiment, a goose was again offered and immediately accepted. So it went on, the snake taking geese, but refusing all other food, such as served for the maintenance of other specimens of the same species."

At the same zoo, Walter Berridge told an interesting story twelve years later: "On one occasion an individual [python] at the London Zoological Gardens dislocated its jaws as the result of swallowing a kid [goat], and this mishap necessitated the attendance of a veterinary surgeon who was called in to operate upon the patient. The snake was held securely by a number of keepers while the surgeon placed the bones into their proper position, after which the greater part of the reptile's head was enveloped in a thick coating of plaster-of-paris, and bound up with a long strip of lint. This treatment eventually proved successful, although the operation had to be repeated a second time, for on the first occasion the snake managed to rub off the dressings that had been applied."

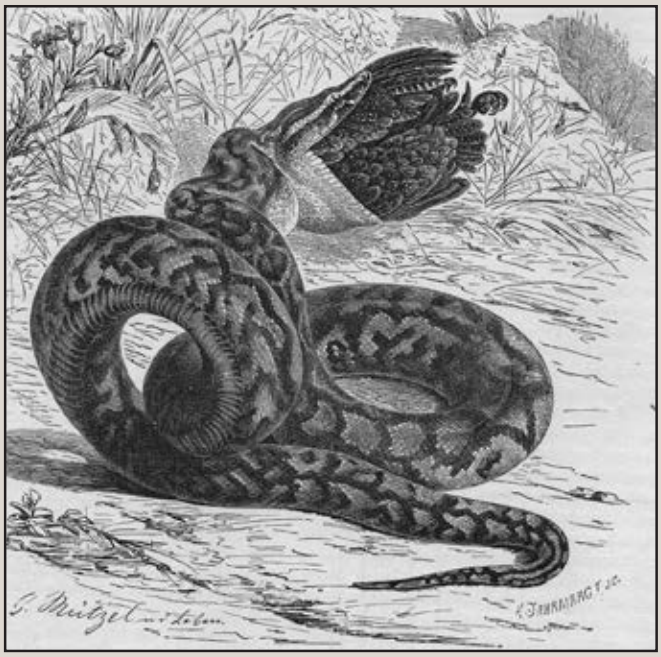
William Lamar sent this email note to me on 1 January 2014, "In the mid-80s Burmese-Retic hybrids made the scene. A clutch was reported on by Matz (in a French journal, with color illustration) and still others (from the wild?) were offered by Louis Porras at The Shed (reptile dealer). Interestingly, the two groups illustrated classic characteristics of hybrids in that phenotypically offspring will generally lean towards one or the other parent. Those reported by Matz were built like retics, with bulging orange eyes, while the ones Porras and others offered were structured like Burms, with an odd olive dorsal color. They were dubbed 'Bornean bat-eating Pythons.' I saw 'boacondas' in 1984 at Blue Ribbon Pet Farm. They were instantly recognizable as anaconda-boa constrictor hybrids. *Epicrates cenchria* and *E. maurus* regularly hybridize in zones of contact in Colombia and Venezuela, and *Corallus caninus* crossed with *C. hortulanus* while both were living in a tree growing in Joep Moonen's patio in Suriname. I have color photos of the *Epicrates* hybrids and of progeny from the Moonen breeding. Fascinating."



There have been three long-term zoo management programs that deserve recognition. Some of the most unusual boas and pythons ever exhibited in a reptile building were displayed in the collection of Houston Zoo, starting around 1965: all three Madagascan boas (*Sanzinia, Acrantophis*), Angolan Dwarf Python (*Python anchietae*), Calabar Python (*Calabaria reinhardtii*), White-lipped Python (*Leiopython albertisii*), Black-headed Python (*Aspidites melanocephalus*), Bismarck Ringed Python (*Bothrochilus boa*), Panamanian Dwarf Boa (*Ungaliophis panamensis*), all of the Pacific boas (*Candoia*), Argentinian Boa (*Boa constrictor occidentalis*), Boelen's Python (*Morelia boeleni*), and many insular Caribbean forms (*Tropidophis, Chilabothrus*) .

Beginning in 1976, Trooper Walsh from Smithsonian National Zoological Park produced nearly 800 neonates of three species: Brazilian Rainbow Boa (*Epicrates cenchria*), Emerald Tree Boa (*Corallus canina*), and Green Tree Python (*Chondropython viridis*) into the third generation (Walsh 1994). Peter Tolson of Toledo Zoo has the most impressive program ever developed for Neotropical boids of the genus *Epicrates* (Chandler and Tolson 1990; Tolson, 1980, 1982, 1987, 1989, 1991, 1992, 1994, 1996; Tolson and Garcia 1997; Tolson and Henderson 2006, 2011; Tolson and Teubner, 1987; Tolson et al. 1983, 2007). His focus on conservation of this snake assemblage includes captive-breeding, reintroduction, and field studies.

Annually, the Association of Zoos & Aquariums (AZA) offers the prestigious Edward H. Bean Award to recognize a truly significant captive propagation effort that clearly enhances the conservation of the species. Bean was the first director of the Brookfield Zoo (Chicago Zoological Society). Since I lived in Chicago, I met him as a child to ask for advice about being a zoo herpetologist and he kindly and patiently answered all of my questions—he enthusiastically supported my dream. He was proud of the Zoo and we spent a lovely afternoon together as he showed me the majestic fountain named after the 26th president of the United States, Theodore Roosevelt, Baboon Island, Bear Grottos, Bird Exhibits, and the Reptile House. As we left the last building during our walkabout, his final message was—"Go for it, young man!" Recipients for the Bean Award for boas and pythons have been Columbus Zoo for Jamaican Boa (1972), Institute for Herpetological Research for White-lipped Python (1976), Reptile Breeding Foundation for Insular Forms of *Epicrates* (1978), Dallas Zoo for Bismarck Ringed Python (1979), Houston Zoo for Angolan Python (1982), Knoxville Zoo for Papuan Python (1986), and Toledo Zoo for Boa Breeding Program (1987).



Pythons

As a rule, pythons do well in captivity so it is not surprising that many papers have been published on their biology, such as locomotory components of python feeding behavior (Murphy

FIG. 5. Photo of a jaunty Roger Conant (right) and zoo keepers outside the old "Proboscidia" Building ca. 1932. Prior to the opening of that beautiful reptile building at Toledo Zoo, the reptile collection was housed in a series of terraria in the visitor viewing area that was called Antler Hall because of all the trophy heads displayed within. The snake is obviously a python—African Rock Python (*Python sebae*) perhaps?

and Campbell 1987). One question asked during the nineteenth century was did pythons attend and brood egg clutches? This controversy raged for many years. Pierre Bernard mentioned that a female python laid 15 eggs, eight of which hatched in Le Jardin des Plantes in Paris (Bernard, 1842–1843, Fig. 3). According to Edward Turner Bennett (1829), in 1828, a python laid and attended 15 eggs in the Tower Menagerie in London which did not successfully hatch. Bennett described the event, " The individual figured at the head of the present article is a female; a fact which was proved by the remarkable circumstance of her producing in May last, after having been more than two years in the Menagerie, a cluster of eggs, fourteen or fifteen in number, none of which, however, were hatched, although the mother evinced the greatest anxiety for their preservation, coiling herself around them in the form of a cone, of which her head formed the summit, and guarding them from external injury with truly maternal solicitude." This account is one of the first to describe brooding in pythons. Forbes (1881) observed incubation of the Indian python at London Zoo and addressed the issue of increasing temperatures during brooding. Hutchison et al. (1966) convincingly documented thermoregulation in a brooding female Indian python at New York Zoological Park. Three papers by Van Mierop and Barnard (1976, 1978) described reproduction and thermoregulation in the Burmese Python. Murphy (2007) and Petzold (see Heichler and Murphy 2008) presented an historical portrait of experiments to determine whether female pythons produce heat when brooding egg clutches.

There are several papers regarding captive management, reproduction, and brooding behavior in African Rock Pythons (*Python sebae*) (Figs. 4, 5) and other smaller species from the region. Sclater (1862) recorded notes on egg incubation in London Zoo. London Zoo Curator Joan Procter raised several snakes to sexual maturity, about 5 years and 10 months (Flower 1937). Frederick William FitzSimons, Director of the Port Elizabeth Museum and Snake Park in South Africa, published a book *Pythons and Their Ways* (1930) that described reproduction (clutch sizes, egg measurements and weights, incubation durations, and neonatal care, based on data from eleven clutches), brooding behavior, and maintenance in African Rock Pythons. Benedict (1932) studied reproductive biology and maternal brooding behavior by comparing environmental and skin temperatures of a female at Smithsonian National Zoological Park. Meyer-Holzapfel (1969) discussed brooding

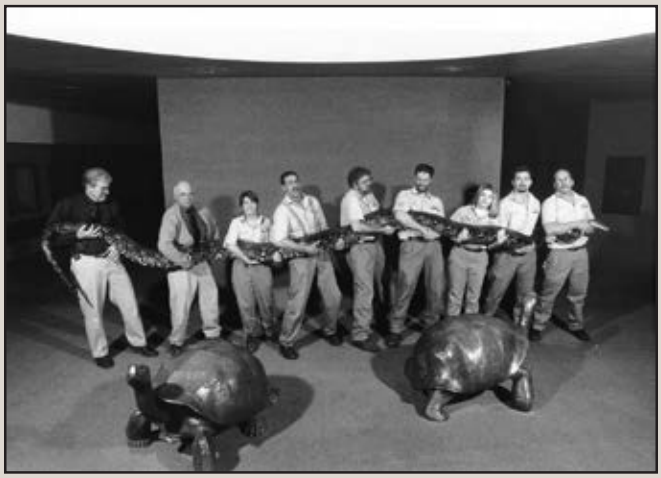

FIG. 6. Head Keeper J. Tyrell with handful of snake ca. 1890 at London Zoo. Many of the larger boas and pythons were kept in zoo collections during this period as these snakes were relatively hardy captives and dramatic exhibits.

behavior at Berne Zoo. Whitworth (1974) followed growth of an African python (and an Indian python) at Cannon Aquarium and Vivarium, Manchester Museum, UK. Branch and Erasmus (1984) described an interspecific hybrid between *P. sebae natalensis* and *P. molurus bivittatus*. Incubation times for *P. sebae* have been reported from 71–77 days at Melbourne Zoo (Dunn 1979), 81–88 days at Transvaal Snake Park (Patterson 1974), and 75–109 days at 30–32.8°C (Ross 1990). Branch and Patterson (1975) described embryonic development in the African Rock Python.

My friend, the late Jack Joy, was General Curator at Dallas Zoo. He had a large collection at home, including an African Rock Python about 13 feet (3.9 m) long. One day while offering a large dead rat with a too short pair of tongs, the snake struck, missed the rodent, latched on to his arm, threw coils around his neck and upper body, and nearly killed him until his terrified wife, screaming all the time, helped untangle him. He admitted that he had been careless and never should have worked with the snake alone; his wife insisted that either he or his snake leave the house immediately but when he hesitated and asked for time to consider the options, she was most displeased —Jack donated the snake shortly thereafter to Dallas Zoo in the interest of marital peace.

Patterson (1974) hatched the African Rock Python and Angolan Python (1978). Branch and Griffin (1996) outlined zoo breeding programs for Angolan Pythons (*Python anchietae*) in the United States and Transvaal Snake Park, South Africa. Ball Pythons (*Python regius*) are also popular zoo exhibits and an extraordinary number of color morphs are being produced in the private sector (see Murphy and McCloud 2010, Barker and Barker 2006). Martin de Camilo et al. (1999) described comparative follicular dynamics between the Ball Python (*Python regius*) and the Brazilian rainbow boa. Reproductive data were provided to Charles R. S. Pitman for his book *A Guide to the Snakes of Uganda* by the Detroit and Houston Zoos in 1974 (see also Logan 1973). Sonibare et al. (2010) provided a case history of eperythrozoonosis (infection with organisms of the genus *Eperythrozoon*, found on erythrocytes and in blood plasmas) in the zoological garden in Ibadan, Nigeria. Richard Ross (pers. comm.) saw brooding female Ball Pythons leave their clutches, crawl into the water bowl, soak for several minutes, and return to coil around the egg mass with moistened bodies. Conant (1993) wrote that a male Ball Python was acquired at Philadelphia Zoo on 26 April 1945 and died on 7 October 1992—reaching the approximate age of forty-seven and one-half years. Jeff Ettling from St. Louis Zoo sent this note—"We do indeed still have the old ball python. It is a female and was accessioned into the collection on 16 February 1958, which makes her 55 yrs, 11 m, 3 d old." This snake is still alive on 20 January 2014.

Indian and Burmese pythons (*Python molurus* and *P. bivittatus*) have been exhibited for many years in zoos (Fig. 6). In the Tower of London, Anacondas, called *Python Tigris* Var. by Bennett, were almost certainly Ceylonese Pythons, *Python molurus pimbura*. One keeper learned the hard way that captive snakes may have impressive feeding responses when one of his pythons grabbed his hand and threw two coils around his neck during feeding. According to Bennett, "His own exertions, however, aided by those of the under keepers, at length disengaged him from his perilous situation; but so determined was the attack of the snake that it could not be compelled to relinquish its hold until two of its teeth had been broken off and left in the thumb." Visser (2003) said that Burmese Pythons (and Boa Constrictors), listed as "creeping animals," were in Rotterdam Zoo collection record in 1858. Lederer (1956) reported upon the reproductive biology and development of the Indian and Burmese Python at Frankfurt Zoo. Golding (1965) followed growth rate of a captive Indian Python at the University of Ibadan Zoo, Nigeria. At Ueno Zoo in Japan, Takahashi (1967) propagated the Indian Python as did Joshi et al. (2001) at Kota Zoo, Rajastan, India. Müller (1970) and Engelmann (1986) documented breeding behavior of the Burmese Python at the Leipzig Zoo. Acharjyo and R. Misra (1976) studied reproduction and growth of the Indian Python at the Nandankanan Biological Park, Orissa, India, followed by another study (Acharjyo and Misra 1980) describing growth rate and age at first egg-laying. Vyas (1996) recorded breeding of the Indian Python at Sayaji Baug Zoo, Vadodara, India. Sekar and Jagnnadha-Rao (1995) outlined management of this taxon at Arignar Anna Sekar Zoological Park, Vandalur, India. Townson (1980) observed reproduction of Indian and Burmese pythons, with interbreeding of the two subspecies. *Python molurus* has been bred to the 3rd generation in Tokyo's Ueno Zoo (Sugiura 1977). At Prague Zoo Rehák (1993, 1994) outlined captive care and breeding of the Ceylon Python (*Python molurus* "*pimbura*") and Indian Pythons. Baskar et al. (1999) examined incubation, feeding and growth of Indian pythons at Arignar Anna Zoological Park, Madras,

COURTESY OF WILDLIFE CONSERVATION SOCIETY HEADQUARTERED AT BRONX ZOO, PROVIDED BY JOHN BEHLER

FIG. 7. An enormous Reticulated Python named "Samantha" was rescued from hide hunters in 1993, was 21 feet (6.4 m) and 175 pounds (79.3 kg) when captured. She grew to over 26 feet (7.9 m) and 275 pounds (124.7 kg) at the Wildlife Conservation Society (Bronx Zoo) until her death in November 2002. Late curator John Behler is on the tail end and his assistant Bill Holmstrom holds the head. This Zoo has offered a reward of US $50,000 for many decades for a snake measuring at least 30 feet (9.1 m) in total length; this reward has never been claimed.

India. Radhakrishnan et al. (2009) listed two species (Sand Boa [*Eryx conicus*] and Indian Python) screened for endoparasitism in captive wildcaught snakes indigenous to Kerala, India. At Smithsonian National Zoological Park, Walsh and Murphy (2003) reported on husbandry, breeding and behavior of Indian Pythons which included neonates with aberrant color patterns. This may have been caused by variable egg incubation temperatures. A captive group of Indian Pythons (4 males,1 female) formed a linear social hierarchy, reinforced by male combat, and bred the female according to their rank (Barker et al. 1979). Fourteen Indian Pythons reared in the Chengdu Zoo in China were trained by gentle human touching and washing snakes with warm water or touching with a warm wet towel. The snakes gradually became tamer and more approachable (Mao et al. 2009). After feeding in the Indian Python at the Smithsonian National Zoological Park, Marcellini and Peters (1982) reported endogenous heat production. Robinson et al. (1978) used radiation therapy for treatment of an intraoral malignant lymphoma in an Indian Rock Python at San Diego Zoo. Barten (1985) described oviductal rupture in a Burmese Python (*Python molurus bivittatus*) treated with oxytocin for egg retention. Groot et al. (2003) presented molecular genetic evidence for parthenogenesis in the Burmese Python at Artis Zoo, Netherlands.

I was visiting some friends from another zoo who had a large tame Burmese Python that was allowed to crawl around the house. One evening, their young son, who reminded me of a miniature Winston Churchill, went into the bedroom to play with the snake. After a few minutes, we heard the words "Bad Snake, Bad Snake" emanating from the bedroom. When we went to check, the child was completely enveloped in coils and it took some time to free him; he survived without any permanent damage. Later, we learned that he had been playing with rabbits in the backyard.

At Dallas Zoo, I was holding a large Burmese Python behind the head while a keeper inserted a catheter tube in its mouth to administer drugs to treat a serious respiratory infection. The snake lunged forward—pulling me along—latched on to his hand, threw coils around both of us, and completely immobilized us. We were unable to extricate ourselves for nearly 30 minutes so we both had to slowly creep on the floor until reaching the snakebite alarm. When we were finally freed by other workers, the now-furious keeper refused to speak to me for several weeks and vividly described my incompetence as a snake wrangler to anyone who would listen, showing his mangled hand with an array of tooth marks as proof.

Lederer (1944) wrote an extensive paper on food supply, development, mating and brood care of the Reticulated Python (*Python reticulatus*) at Frankfurt Zoo. Honegger (1970) published his study on the reproductive biology. In the vivarium of the Château de Thoiry-en-Yvelines near Paris, Panouse and Pellier (1973) recorded oviposition and incubation of the eggs in this taxon. Araki et al. (1982) reproduced this python at the Takarazuka Zoological and Botanical Gardens in Japan and included photographs of the facility and reproductive events. Ovezmukhammedov et al. (1975) diagnosed parasites of the reticulated python from the Ashkhabad Zoo, Turkmenistan. Taiwo et al (2002) found ascaridosis in captive Reticulated Pythons. Baumgartner et al. (1987) diagnosed tubular adeno-cancer in the colon of a Reticulated Python. At Dallas Zoo, a large Reticulated Python was bitten on the tail by a Brown Recluse Spider (*Loxosceles reclusa*). In spite of medical care, the site became progressively more necrotic and the necrosis began expanding and moving anteriorly. The tail was eventually amputated.

An enormous Reticulated Python named "Samantha" was rescued from hide hunters in 1993, was 21 feet (6.4 m) and 175 pounds (79.3 kg) when captured. She grew to over 26 feet (7.9 m) and 275 pounds (124.7 kg) at the Wildlife Conservation Society (Bronx Zoo) until her death in November 2002. Her favorite food was pigs (Fig. 7). Kamuran Tepedelen from Bushmaster Reptiles, Inc. in Colorado located and sent the snake to the Zoo and what follows is his account of the saga of acquiring Samantha in the beginning. In 1993, curator John Behler was contacted by a hide dealer in Borneo, claiming that he had a live 30 foot (9.1 m) Reticulated Python that had been collected in the interior of Borneo. The Zoo had a standing offer for decades to issue a reward of $50,000 for any snake that long but the reward had never been claimed. John was skeptical but Tepedelen was in Indonesia at the time and offered to check the snake's length. The snake was being held in an empty railroad boxcar, along with another male about 16 feet in length; both were coiled together. Kamuran crawled into the dark interior with a bamboo stick and tried to prod the male to move away so he could get an accurate measurement but the smaller snake struck repeatedly at him. Finally, the male moved away and Tepedelen, with two helpers, descendants of the Dayak tribe, tried to entice the snake to crawl into a large burlap bag but it would only move a short distance into the sack and pull back out quickly. This went on for over an hour until he grabbed the snake behind the head and the others grabbed the snake's body. As can be imagined, the snake went ballistic, throwing coils around Tepedelen's body and knocking him to the floor. Samantha was finally stuffed into the bag but it had been uncertain as to whether snake or humans would prevail—the snake was unbelievably powerful. The measuring of the snake (about 22 feet [6.7 m] in length) and initial crate building was done in Borneo at the skin dealer's compound. Kamuran spent an entire day trying to get a phone call back to Behler to let him know the true size of the snake and its condition, before the final

FIG. 8. Illustration of Black-headed Python (*Aspidites melanocephalus*) from *Snakes of Australia* by Gerard Krefft (1869). These snakes regularly excavate burrows by forming the head and anterior trunk into a "J" configuration, moving sideways, and pulling the substrate trapped by the head-neck angle toward the posterior trunk.

deal was struck with the dealer at a much lower price. The hide dealer was disappointed and suggested that the snake be hung by its neck from a tree to stretch it another 8 feet but Kamuran demurred. The first step was to get CITES permits and other documents and this was done. The next was to build a shipping crate but Kamuran was not precise about measurements when dealing with the local carpenter. When the box arrived it was one foot wide and one foot high and twenty feet long (0.3 × 0.3 × 6.0 m). Another crate was quickly built (6 × 3 × 2 ft /1.5 × 1.0 × 0.6 m) and the snake packed for shipment to New York; snake and crate were so heavy, a forklift truck had to be used—the trip was uneventful and took eight days from start to finish—an amazingly short time! In his wonderful book *Tracks and Shadows* (2013; p. 143), Harry Greene from Cornell University describes the awe one feels when viewing this large snake: "About the same time as those Cornell connections were established I met an exceptionally large snake while visiting the Bronx Zoo with my herpetology class. Samantha was a reticulated python, wild caught as an adult and almost twenty-three feet long. She had an enormous head, perhaps for having in youth eaten larger prey than her captive fare of forty-pound piglets, and given inclination and opportunity she surely could have swallowed me. I looked through the glass cage front and imagined her back in Borneo, moving rectilinearly like an immense caterpillar over dank forest substrate. What would it be like in her world of chemical and tactile sensations, I wondered, with one's head so far from one's tail. And out in nature, how would her presence affect other creatures?" Greene's comment about the size of Samantha's head resonated with me as I have seen many captive boas and pythons with seemingly disproportionally small heads. We had a Reticulated Python that grew to nearly 20 feet (6.0 m) in length at Dallas Zoo sent to us by the late Wesley Dickinson in 1966; he shortly thereafter died from a King Cobra bite (see Murphy and Jacques 2006). He said that the snake was raised in captivity throughout virtually all of its life. In a photo in our paper (Murphy and Jacques 2006), the size of the snake's head is small. A group of wild-caught snakes ranging in length between 10–12 feet (3.0–3.6 m) was imported and I compared relative sizes of their heads with our larger snake—they were about equal. I suspect that captives are fed too much food and abnormal body growth outstrips normal skull development.

Thomas Headland and Harry Greene (2011) recorded these snakes preying on 10 species of Old World monkeys, and a Siamang (*Hylobates syndactylus*). There is a radiograph in their paper of two Lion-Tailed Macaque juveniles swallowed headfirst by a Reticulated Python. Anthropoid apes have not been recorded as prey (Greene, pers. comm.). In 1986 during employment with Smithsonian National Zoological Park, William Xanten went to the Sepilok Orangutan Rehabilitation facility in Sabah, Eastern Borneo, which for years maintained both orphaned and injured Orangutans (*Pongo pygameus*) for rehabilitation and eventual release. Two young orangs that appeared to be about two years of age had been kept in an outdoor, barred enclosure. A large snake approximately 12–15 ft (3.65–4.55 m) in total length was inside the cage with two distinct lumps about half way down the body. Because the bars were close together, the snake was unable to escape after dinner. Xanten asked the staff what they intended to do with the python. They shrugged their shoulders and said that the python was only doing what was natural for a snake. They would keep the python on exhibit in another area from which it could not escape (Xanten 2014, pers. comm.). The length of another Reticulated Python named Colossus at Pittsburgh Zoo was often exaggerated. The photo caption in Pope (1961) says that it was 28.5 feet long (8.7 m), 37.5 inches (0.9 m) in girth and has an estimated weight of more than 320 pounds (145 kg). Its true length was 6.35 m (20 ft 10 in) at necropsy (Barker et al. 2012).

In two papers from Dallas Zoo, Murphy et al. (1978, 1981) recorded the reproductive biology of nineteen species of boas and pythons, genera *Acrantophis, Aspidites, Candoia, Corallus, Epicrates, Liasis,* and *Python*. Three pythons were described in the 1978 paper: courtship in Boelen's Python (*Python boeleni*), and oviposition in Carpet Python (*Python spilotus*) and Timor Python (*Python timoriensis*). Wallach (1975) performed a partial gastrectomy in a Timor Python. From Trinidad Zoo, Boos (1979) listed breeding records of Australian pythons. Barker (1984) and Murphy et al. (1981) reproduced Black-headed Pythons (*Aspidites melanocephalus*) at Dallas Zoo (Fig. 8). Johnson et al. (1975) mentioned that a wild snake was removed from a termite mound in Australia—"Upon removal, the python was found 12.5 to 15 cm below the substrate surface packed in a tight, circular coil in what appeared to be a chamber excavated by the python." The snakes (2 males,1 female) mentioned in our 1981 paper regularly excavated the gravel substrate in their enclosures, usually near

an object: "Excavation was accomplished by forming the head and anterior trunk into a 'J' configuration, moving sideways, then pulling the gravel entrapped by the head-neck angle toward the posterior trunk. The female dug continuously from the time of copulation until oviposition." This female is shown wrapped around a clutch of eggs in Barker and Barker (1994). All of our snakes rested on the substrate but elevated their heads at least a foot (30.5 cm) in a vertical plane almost every morning to be nearer the heat lamp on top of the enclosure. Twin Black-headed Pythons hatched at Houston Zoo in 2005.

Ross (1973) described mating and hatching of Children's Python (*Liasis childreni*), Dunn (1979) bred the species at Melbourne Zoo, and reproduction was recorded at Dallas Zoo (Murphy et al. 1981). Ross and Larman (1977) reproduced two species, White-lipped or D'Albert's (*Liasis albertisii*) and Macklot's pythons (*Liasis macklotí*), at Institute for Herpetological Research in California. At Dallas Zoo, courtship behavior and reproduction was reported (Murphy et al. 1981). Banks (1985) reproduced the White-lipped Python at Melbourne Zoo. Porter et al. (2012) reported on natural history and captive management of the Rough-scaled Python (*Morelia carinata*). Ryabov (1999) bred the Stimson's Python (*Antaresia stimsoni orientalis*) at Tula Exotarium in Russia. Bels and Van den Sande (1986) described reproduced the Australian Carpet Python (*Morelia spilota*) at the Antwerp Zoo. Grow et al. (1988) reproduced the Amethystine Python (*Python amethystinus kinghorni*) and Tarbet (1983) the D'Albert's Python (= White-lipped Python) at Oklahoma City Zoo. Korzhov et al. (1995) bred the Indonesian Scrub Python (*Liasis a. amethistinus*) at Moscow Zoo and Boos (1972) described reproduction in captivity that included female body twitching around eggs. Peters (1975) observed body twitching at Taronga Zoo in Sydney. Bryant et al. (1997) used cryosurgery in a Diamond Python (*Morelia s. spilota*) with fibrosarcoma at Taronga Zoo.

Tryon and Whitehead (1988) reproduced the Papuan Olive Python, (*Liasis papuanus*) at Knoxville Zoo, and Odinchenko and Latyshev (2011) at Moscow Zoo. I know of two instances where Olive Pythons have killed and/or swallowed snakes larger than themselves. Alan Kardon from San Antonio Zoo sent the following note to me, "Shortly before my June 1976 arrival, an 11 foot Papuan Python constricted and killed an 18 foot Reticulated Python. They had been housed together in one of our large center exhibits. A large Burmese Python also resided in the same exhibit. The Papuan Python did not consume the retic. Staff pried off the Papuan and the deceased retic was skinned. It was on display for many years in our administrative office. It now resides with San Angelo State College." Richard Ross (pers. comm.) kept an eight-foot (2.4 m) *Apodora papuana* in a large enclosure with a slightly longer Carpet Python (*Morelia spilota*). The cage was subdivided so the two snakes were separated with a plywood barrier attached to the front, top, and bottom. There was a small gap (2 cm) at the back. The Olive Python wedged its head into that tiny space and literally bent the plywood barrier as it squeezed into the Carpet Python's space and consumed it. Its body was so distended, the interstitial skin was visible. The meal was completely digested. This snake bit and constricted Ross. The snake was so powerful and the bite so bloody and painful that he nearly fainted from the ordeal—it was the most serious accident of this nature he ever experienced.

Some years ago, I saw an excellent but sobering presentation at the AZA Snake Taxon Advisory Group (TAG) meeting in Baltimore about the natural history and captive management of the beautiful but poorly known Boelen's Python (*Morelia boeleni*) from New Guinea. This taxon has been extensively studied by Marc Spataro of The Boelen's Python Group <www.boelenspythons.com>. He has experience in the field with this snake; it inhabits forested montane regions of over 1000 m (3300 ft) elevation and the terrain is exceedingly difficult to traverse. What was particularly disconcerting were the photographs in his talk showing the extraordinary damage caused by strip mining at the world's largest gold mine and third largest copper mine, owned by the American mining company Freeport-McMoRan. The whole area looked like a moonscape. I asked Marc to predict the likely future for Boelen's Python if mining continued unabated—he was very pessimistic and I could not help but agree. Austin et al. (2010) studied conservation genetics and warned of reduced genetic diversity and divergence of captive and wild animals. Many zoos donated genetic material for this study. At Dallas Zoo, courtship and reproduction were observed (Murphy et al. 1978, 1981) but unfortunately no full-term neonates were produced. Flagle and Stoops (2007) discussed reasons why this species has been such an enormous challenge to create sustainable reproductive colonies in captivity. West et al. (2001) found meningoencephalitis associated with paramyxovirus infection in a Boelen's Python at San Antonio Zoo.

We had four Bismarck Ringed Pythons (*Bothrochilus boa*) at Dallas Zoo from Rabaul, Great Britain Island and unknown localities—intermittent courtship was seen. Eggs were laid and hatched and the young were spectacularly colored—vivid orange bands which began to disappear around three months and became olive brown three months later (Murphy et al. 1981). Clearly, my bias is showing here but had these pythons retained that dramatic juvenile coloration through adulthood, they would have likely supplanted the Brazilian Rainbow Boa as the most beautiful boa or python.

Several studies by Walsh and associates at Smithsonian National Zoological Park (Van Mierop et al. 1982; Walsh, 1977, 1980) documented behavior, husbandry and breeding of the Green Tree Python (*Chondropython viridis*). Brannian et al. (1980) from the Kansas City Zoological Gardens focused on mortality in captives. Mannion (1996) propagated the Green Tree Python at the Queensland Reptile and Fauna Park. Rundquist (1980) described twinning at Oklahoma City Zoo, likely the first description of this occurrence in pythons. At the same zoo, Blakeley and West (1977) saw no brooding behavior; eggs were scattered throughout the enclosure. At Dallas Zoo, Murphy et al. (1978) observed caudal luring in neonates. Perry-Richardson (1991) described male combat that resulted in death of one of the snakes. Fourteen hybrids between a Green Tree Python (dam) and Carpet Python (sire) hatched (one stillborn) at Baltimore Zoo during February 1997. One female now lives at Catoctin Zoo in Maryland (K. Kranz, D. Middaugh, pers. comm.). Total length is ca. 6 ft (1.8 m) and the snake is heavy-bodied like a wild Carpet Python but its head is shorter and wider like a Green Tree Python; ground color is light lime green with white-tipped scales and pattern remindful of a Carpet Python. Its nickname is "Carpondro."

At Dallas Zoo, Clay Garrett and Brian Smith (1994) wondered if yellow and brown hatchling Green Tree Python morphs would match their color—when given a choice of differently colored backgrounds—to blend in to avoid predation and be less noticeable to prey. For example, would a yellow neonate "know" that it would be more visible to a predator if it rested on a dark branch rather than on a light one and would the snake

Fig. 9. "Note on *Python curtus*" was published by G. A. Boulenger in Proceedings of The Zoological Society of London in 1889 (432–433). As of Jan. 24, 2014; source = ZIMS (ISIS), there are 37 Blood Pythons (*Python curtus*), 11 *P. breitensteini*) and no *P. kyaiktiyo* represented in zoo collections worldwide.

PHOTO BY JACK MUNTZER, COURTESY OF ROBERT ZAPPALORTI

Fig. 10. Carl F. Kauffeld and Boa Constrictor "Blondie," taken at Staten Island Zoo in October 1967. He was one of the most productive authors, as is evident by his chapter entitled "So you own a boa" in *Snakes: The Keeper and the Kept* in 1969.

"know" that the likely better choice would be the light one? One hatchling of either color phase was placed in a large trash can with a T-shaped perch made with painted dowel rods and wooden bases. The snakes were allowed to choose between black and white or yellow and brown halves of the T-perch. Only one perch was used per trial. In the beginning of the experiment, the snakes would crawl around the perimeter of the can for many hours until they found the perch in the center and assumed an ellipsoidal coil on the horizontal bar. Once the snakes were comfortably settled, their location (either light or dark side) was recorded. As the experiment progressed, the length of time to find the perch diminished until the end when the snakes located the perch in less than a minute. Later, when these snakes (both brown and yellow color phases) were given a choice between dark and light perches, most of the snakes more often chose the darker side as a resting site.

One aspect that is interesting to me and was not part of the original study was the snakes learned the location of the perch, rapidly ascended the vertical dowel, and quickly coiled on the horizontal bar by the end of the study. Most studies on learning behavior in snakes use food as a reward but in this case, no food was involved. Our snakes were certainly learning the location of the perch and presumably choosing it as a more secure resting place rather than simply coiling on the bottom of the can. The fact that they more often chose the darker side regardless of their color was unexpected as I had predicted that the snakes would match the background. One of my colleagues told me that he discovered a reddish juvenile Annulated Boa (*Corallus annulatus*) coiled on a large green leaf in plain view in a Costa Rican forest and the snake was virtually invisible because of the dappled sunlight streaming through the canopy. See Wilson (2006) and Wilson et al. (2007) for additional information.

Ettling (1991) elaborated on captive husbandry and reproduction of the Blood Python (*Python curtus*) and Hilf et al. (1989) investigated pharmacokinetics of Gentamicin and Piperacillin at St. Louis Zoo (Fig. 9). Noble (1935) described brooding behavior at New York Zoological Society. Rehák (1994) bred Blood Pythons (*Python curtus breitensteini*) at the Prague Zoo. At Dallas Zoo, we received two wild-caught adult snakes that refused to feed until we added a large pile of dried leaves to the enclosure for security. Hilf et al. (1990) did a comparative study of upper airway flora in healthy boid snakes and snakes with pneumonia at the Pittsburgh Zoo.

Boas and Anacondas

Representatives from the New World are often exhibited in zoos. Müller (1970) bred the Boa Constrictor (*Boa constrictor*) at Leipzig Zoo. Honegger (1970) published a paper on the

Fig. 11. Maria Sibylla Merian understood the importance of careful observations when she drew this Garden Tree Boa (*Corallus hortulana*) with a sizeable meal from *Metamorphosis insectorum surinamensium*… in 1705.

reproductive biology of the subspecies *B. c. imperator* which has been bred through the second generation at Zurich Zoo. Gensch (1969) reported on boa hybrids *Constrictor* (=*Boa*) *c. constrictor* × *C. c. imperator* at the Dresden Zoo. Meyer-Holzapfel (1955) described a cross between *Constrictor c. occidentalis* × *Constrictor c. constrictor* at Berne Zoo. Luttenberger (1964) recorded a *B. c. occidentalis* × *B. c. constrictor* cross at Tiergarten Schönbrunn. A Boa Constrictor (*Boa constrictor*) at Dallas Zoo showed color change over time between feedings (Hedges et al. 1989). After feeding, the ground color was dark and as the interval between feedings increased, the pinkish color became lighter and lighter. This was our signal that it was time to offer food. Moore and McLaughlin (1981) surveyed boid care and use in education programs in American zoos. Carl F. Kauffeld at the Staten Island Zoo was one of the most knowledgeable authors, as is evident by his chapter entitled "So you own a boa" in *Snakes: The Keeper and the Kept* in 1969 (Fig. 10). He addressed feeding and manipulation of odor as an aid in feeding captives, treatment of mouthrot, removal of abnormal eggs by sectioning, mites and ticks, cage sanitation, the effect of altitude, ultraviolet light, and humidity on captive reptiles, shedding, and the importance of environmental factors such as temperature. He stressed the need for security, maintaining them singly, and offering pre-killed food. Using Boa Constrictors and Gaboon Vipers from Zoo Atlanta to study movement, Marvi et al. (2013) found that snakes mimic earthworms by using rectilinear travelling waves.

Blody and Mehaffey (1989), Murphy et al. (1978), and Tryon (1975) documented the reproductive biology of the Annulated Boa (*Corallus annulatus*) at Fort Worth Zoo. At this zoo, courtship, parturition, and neonatal color change for Emerald Tree Boa (*Corallus canina*) were recorded by Murphy et al. (1978). Meyer-Holzapfel (1969) bred this species at Berne Zoo. Richard Ross (1990) described the condition of chronic regurgitation of food in this species as "Regurgitation Syndrome" and believed the malady to be cause by lack of humidity. Others have postulated that the condition is caused by cryptosporidiosis, parasitism, amebiasis, and bacterial or fungal gastroenteritis. Environmental factors have been identified: lack of security, handling after feeding, and temperature. Ross (pers. comm.) recently visited a serpentarium in Quito, Ecuador where he saw these snakes in the peak of health. He asked if the caretakers had ever dealt with this syndrome; the answer was negative. When he explored reasons for this, he discovered that heat tapes had been inserted in hollow branches and the snakes coiled directly over the tapes, even though a thermal gradient was available. Digestion was uneventful. Could this problem, known and discussed by virtually every breeder of these snakes for decades, be solved simply by providing heated branches to improve digestion? Pizzatto and Marques (2007) and Pizzatto et al. (2009) described the reproductive ecology of Brazilian boine snakes, including Garden Tree Boas (*Corallus hortulanus*; Fig 11). Robert W. Henderson and colleagues have written about the genus *Corallus* and West Indian taxa (Tolson and Henderson 1993; Stafford and Henderson 1996; Henderson 2002). Henderson et al. (2013) discussed the sharp declines of Grenada Tree Boas (*Corallus grenadensis*) possibly caused by illegal collecting, based on a study by herpetologists from Milwaukee County Zoological Garden, Buffalo Zoo, and Milwaukee Public Museum.

Thomas Huff from the Reptile Breeding Foundation in Canada published a number of papers on reproduction of insular boids of the genus *Epicrates*: Cuban Boa (1976), Puerto Rican Boa (1978), Jamaican Boa (1979), and an overview of the genus in 1980. Murphy and Guese (1977) observed reproduction in the Hispaniola Boa (*Epicrates f. fordii*) at Dallas Zoo. Murphy et al. (1978) observed reproduction in the Hispaniola Boa (*Epicrates g. gracilis*) at Ft. Worth Zoo and courtship and birth of the Cuban Boa (*E. angulifer*) at Dallas Zoo. Bloxam (1982) reported on the care of the Jamaican Boa in Jersey Wildlife Preservation Trust. Brazilian Rainbow Boas (*Epicrates c. cenchria*) reproduced at Smithsonian National Zoological Park (Walsh and Davis 1983; Walsh 1994). Kinney et al. (2012) described parthenogenesis. A snake from Wacará, Vaupés, Colombia gave birth to 18 live, two dead, and one infertile egg mass at Ft. Worth Zoo (Murphy et al. (1978). Holmstrom and Behler (1981) saw *E. cenchria* feed upon unfertilized egg masses and fetal membranes at Bronx Zoo. Jacobson (1993) sounded an alert concerning infectious diseases for captive propagation and introduction programs of threatened and endangered reptiles. Concern for the future of many insular species such as the Puerto Rican Boa (*Epicrates inornatus* now *Chilabothrus inornatus*) has been identified as a conservation priority by zoo workers (Joglar et al. 2007).

Boas from Madagascar are popular zoo exhibits and there have been a number of papers written about them (Branch and Erasmus 1977; Murphy et al. 1978, 1981; Branch 1981, Morgan 1985; Chai et al. 2004; Hydeskov et al. 2012). Madagascan boas

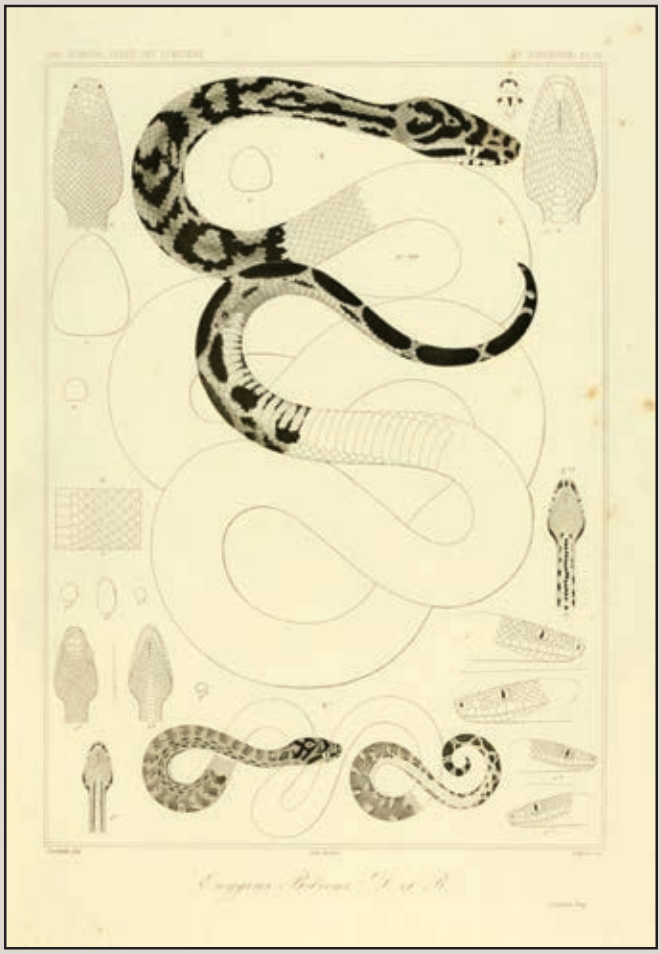

Fig. 12. The Pacific Boa (*Enygrus bibroni* now *Candoia bibroni*) is capable of dramatic daily color changes. Plate from *Iconographie Générale des Ophidiens* by Georges Jan and Ferdinando Sordelli in 1860–1866. This remarkable publication covered snakes of the world and the quality of the illustrations is beyond reproach.

(*Sanzinia madagascariensis*) used pelvic spurs to stab other males during combat at Dallas Zoo (Carpenter et al. 1978). At this zoo, we were interested in breeding them so we had two pair in the collection. Each time we paired them for breeding, the same outcome occurred. One male was accepted immediately by the female and breeding occurred, to the point where the male's hemipenes were ground off by all the frenzied sexual activity. When the other male was placed with the female, both snakes crawled as far away from each other as possible and never bred. Clearly, the snakes recognized each other but I am not sure if it was female choice, male choice, or both. What I do know is that neither snake was interested in breeding and the same result occurred during many trials. Groves and Mellendick (1973) bred this species at Baltimore Zoo as did McLain (1983) at Houston Zoo. A specimen lived for 19 years, 5 months, and 17 days at Philadelphia Zoo (Conant and Hudson 1949). Branch and Erasmus (1976) recorded reproduction in Madagascar Ground Boas (*Acrantophis*) and Tree Boas (*Sanzinia*). Huff (1984) outlined husbandry and propagation of the Madagascar Ground Boa with additional notes on other Malagasy boids at the Reptile Breeding Foundation. Reichling (1983) reproduced the Dumeril's Boa (*Acrantophis dumerili*) at Memphis Zoo. Murphy et al. (1981) saw male combat with biting, constriction on the subdominant snake's trunk, and vigorous spur vibration, followed by the dominant male copulating with the female. At Black Hills' Reptile Gardens in South Dakota, a three-foot (0.9 m) *Acrantophis dumerili* consumed an equal-sized Cuban Boa and another smaller *Acrantophis dumerili* killed and ate a young Boa Constrictor at Catoctin Zoo (Don Middaugh, pers. comm.).

Timmis (1969) observed Pacific boas (*Candoia* spp.) at Taronga Zoo in Australia. At Dallas Zoo, we had an adult Pacific Boa (*Candoia bibroni;* Fig. 12) from Western Samoa that demonstrated dramatic daily color change (Hedges et al. 1989). Each morning, the snake's ground color was blackish and no pattern was visible. As the day progressed, the snake's color lightened until the ground color was light and the pattern clearly defined. We also saw courtship with spur use from males from Kandavu, Fiji Islands. These males used spurs to position female vents for intromission and forced them by repeated jabbing to elevate tails to receive the hemipenes. I was amazed that males knew precisely where to probe female bodies for alignment of cloacae to achieve successful breeding (Murphy et al. 1978). A Pacific Boa (*C. carinata*) from Solomon Islands gave birth to 64 stillborn young (Murphy et al. 1978).

Lederer (1942) described reproduction and development in the Yellow Anaconda (*Eunectes notaeus*) at Frankfurt Zoo. Luttenberger (1984) reported on feeding, husbandry, and reproduction at Tiergarten Schönbrunn in Vienna. Belluomini and Veinert (1967) had breeding Anacondas (*Eunectes murinus*) at São Paulo Zoo and Deschanel (1978) at Lyons Zoo in France. Additional observations were published by Luttenberger (1973). At Dallas Zoo, a large adult living in a semi-aquatic exhibit would only accept freshly-killed geese placed in the water as food. If a goose was placed on land, it was refused. There has been a long-term study of Anacondas in the Zoo and in the wild by employees at the Wildlife Conservation Society (New York Zoological Park, also known as Bronx Zoo. Holmstrom (1981) propagated the Yellow Anaconda and Holmstrom and Behler (1981) recorded post-parturient behavior of the Common Anaconda. Calle et al. (1994, 2001 and Rivas et al. (2007) described studies done in the wild. Raphael et al. (1996) described a technique for implanting transmitters. McNamara et al (1994) found cryptococcosis. Frolov et al. (1986) reproduced the Paraguayan Anaconda in the Moscow Zoo, including second generation births (Kudryavtsev and Odinchenko, 1986). Dunn and Conant (1936) described the Dark-spotted Anaconda *(Eunectes deschauenseei)* and Barbour's Anaconda (*E. barbouri*), which has now been synonymized with *E. murinus*. Retired Detroit Zoo curator Jim Langhammer (pers. comm.) had a large female Barbour's Anaconda which he used for demonstrations while employed as a naturalist in Indiana. He told me that he would release "Annie" among the several hundred visitors and the snake would crawl slowly through the throng until her owner was located, then climb slowly up his trunk and rest its head on his shoulders. The behavior was demonstrated during warm weather at McCormick's Creek State Park and on the campus at Indiana University-Bloomington (IU). She was often called IU's most popular coed by the adoring crowds. She never bit a human even when under medical treatment. Hans-Günter Petzold from Tierpark Berlin wrote the definitive book on the genus in 1983—*Die Anakondas, Gattung* Eunectes—which covers systematics, morphology, natural history, reproduction, and representatives of the genus.

There are limited reports from zoos on some of the smaller boas and pythons, due in large part to their secretive nature which makes them unsuitable for display: Calabar Burrowing Python (*Calabaria*), Rubber Boas (*Charina*), Sand Boas (*Eryx*), Rosy

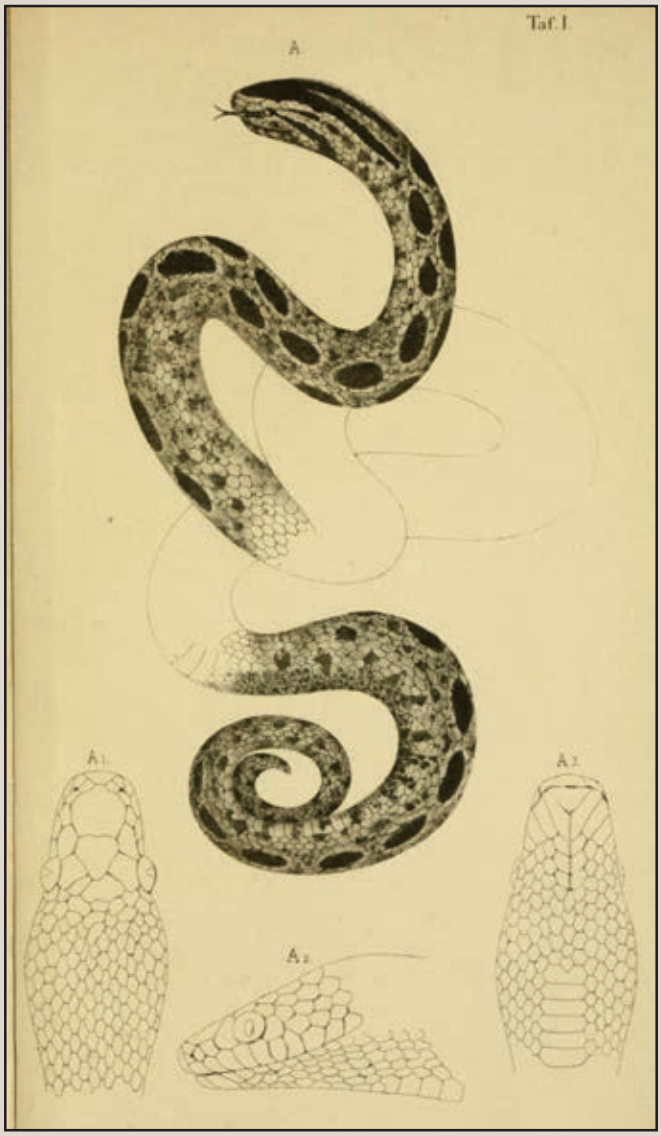

Fig. 13. Holotype of Isthmian Dwarf Boa (*Ungaliophis continentalis*) from Fritz Müller (1878), *Katalog der im Museum und Universitatskabinet zu Basel aufgestellten Amphibien und Reptilien nebst Anmerkungen*. Most living dwarf boas, such as Panamanian Dwarf Boas and Isthmian Dwarf Boas, are no longer represented in any zoo collection worldwide as of Jan. 24, 2014; source = ZIMS (ISIS).

Boas (*Lichanura*), and Mexican Burrowing Python (*Loxocemus*). Odinchenko and Latyshev (2011) kept the last species at Moscow Zoo.

Dwarf Boas

Here I restrict dwarf boas in this section to four New World genera (*Ungaliophis*, *Exiliboa*, *Tropidophis*, and *Trachyboa*). I have been fortunate to see living examples of all in zoo collections and to have worked with all but the last one at Dallas Zoo. In the mid-1970s, M. J. Corn (1974, pers. comm.) told me that he found six Panamanian Dwarf Boas (*Ungaliophis panamensis*) in an area in the Caribbean lowlands in Costa Rica which was being cleared, presumably for agriculture. Only three specimens were known prior to his discovery. These arboreal snakes, living in detritus in epiphytes, were dislodged from their living space and were found by Corn crawling on the ground. I have seen two snakes living at Houston Zoo and we had one in Dallas that adjusted well to captivity. Roger Conant (1966) pointed out that the Isthmian Dwarf Boa (*U. continentalis*) was known from two specimens (Fig. 13). Bogert (1968a) stated, "Since the small boa that became the holotype of *Ungaliophis continentalis* was discovered in Guatemala well over 90 years ago, only six additional snakes of the genus have been reported…These dwarf boas tolerate environments ranging from the lowland rain forest of southeastern Nicaragua to those of the pine woodland of eastern Chiapas, where Conant (1966) discovered one at an elevation of approximately 2100 meters." Imagine my surprise when Barry Armstrong and Jon Campbell brought back three snakes for the Dallas Zoo collection from Chiapas, Mexico—these proved to be hardy in captivity and fed with gusto on small mice and anoles. Both species (*U. panamensis, U. continentalis*) of these Dallas snakes are pictured in the SSAR *Catalogue* account by Villa and Wilson (1990). Burger and Ford (2007), based on the animals at Dallas Zoo, described courtship and reproduction in *U. continentalis*. After decades of field work, Campbell (pers. comm.) has since collected an additional dozen specimens.

I met my first Oaxacan Dwarf Boa (*Exiliboa placata*) at the Southwestern Research Station in Portal, Arizona in 1967. Charles (Chuck) Bogert returned from Mexico with a living one, collected at Valle Nacional at the base of the northern slopes of the Sierra de Juárez, and asked me to identify it. To add to the pressure, he said that if I were unable to do so, it would indicate that I could no longer call myself a competent herpetologist and all of the visiting herpetologists in the room would be aware of my incompetence; the word would be spread widely in the community. He placed the snake in my hand, whereupon it promptly exuded the aforementioned musk. Of course, I could not identify it so Chuck, being somewhat perverse and enjoying my discomfort, continued the ruse for what seemed like eternity until he finally confessed that it was not yet described. Every time we met thereafter, he would laugh heartily at that incident although I was less amused. In subsequent years, Barry Armstrong and Jon Campbell brought back a small number of these snakes to Dallas Zoo and these were an enormous challenge to maintain in captivity. Bogert's captive specimens fed on the frogs *Eleutherodactylus mexicanus* and *E. decoratus* (Bogert 1968b). We tried every food item available (salamanders, frogs, toads, lizards, neonatal mice, small snakes, insects) and all were ignored. Campbell even collected some topotypic frogs (*Craugastor*) and salamanders (*Pseudoeurycea*) to try to stimulate these snakes to feed—only one salamander was accepted. Two gave birth to the tiniest neonates imaginable—we did not even try to feed them but preserved them soon thereafter. William Lamar kept one (pers. comm.), "I kept it in a cage in the refrigeration chamber at UTA and got it to feed on *Acris*. The experiment terminated abruptly when there was a malfunction causing the refrigerator to go from 60° Fahrenheit to around 60° Centigrade."

Edwards (1969) covered care of some tropidophid snakes at Dallas Zoo. The male Cayman Island Boa (*Tropidophis caymanensis parkeri*) he mentioned was received on 1 Feb 1967 and died on 17 Mar 1994 (27 Y, 1 M, 16 D). Rehák (1987) observed color change and captive reproduction (1990) in the Cuban Dwarf Boa (*Tropidophis feicki*) at the Prague Zoo. He also recorded color change in several other *Tropidiphis* and published husbandry observations on the poorly known Ambergris Cay Dwarf Boa *T. greenwayi* (Rehák 1981). Groves (1969) bred the Cayman Island Dwarf Boa (*Tropidophis melanurus caymanensis*)

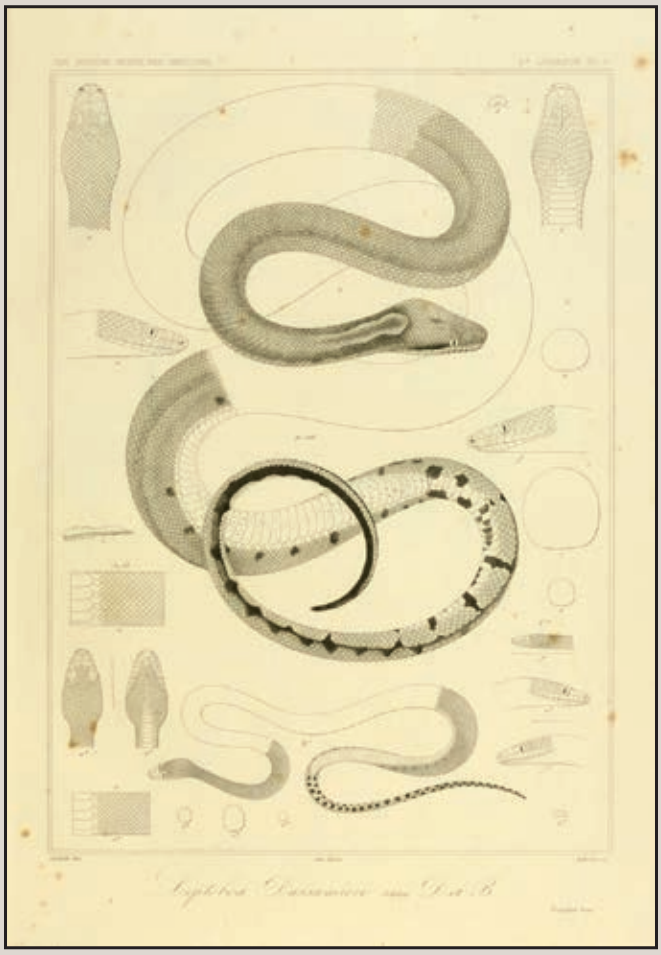

Fig. 14. Illustration of endangered Round Island Splitjaw Snake (*Casarea dussumieri*) from *Iconographie Générale des Ophidiens* by Jan and Sordelli in 1860–66. The only institution holding these snakes, numbering ten specimens, is Jersey Wildlife Preservation Trust as of Jan. 24, 2014; source = ZIMS (ISIS). The Round Island Burrowing Splitjaw Snake (*Bolyeria multocarinata*) is now extinct, due to human causes. Macklot's Python (*Liasis mackloti*) is also pictured.

at Baltimore Zoo. Tolson (1980) covered captive propagation of the Cuban Dwarf Boa (*Tropidophis melanurus*). This taxon was bred at Tierpark Berlin by H.-G. Petzold and adults and young are pictured in Heichler and Murphy (2008). He sent some adults to Dallas Zoo but these did not reproduce there. Petzold also mentioned death-feigning in this genus (Heichler and Murphy (2008).

The only living Eyelash Boas (*Trachyboa*) I have seen were at the Cincinnati and Houston Zoos, described by Arnett et al. (1992) and McLain (1983). The late Johnny Arnett had both species (*T. gularis, T. boulengeri*) in Cincinnati and when he pulled them out from their containers to show me, they were ramrod straight and stiff—these snakes reminded me of the Tentacled Snake (*Erpeton*). Lehmann (1970) pictured this straight (and coiled) defensive posture. I was surprised when Arnett told me that the snakes refused anoles, frogs, and mice but fed on goldfish. The Houston Zoo had *T. boulengeri* in the collection that fed on goldfish.

There is no question that zoo snake collections are becoming homogenized and I now rarely see new taxa when visiting other zoos. As an example, there are no living examples of the following dwarf boas worldwide in ISIS zoos—Panamanian Dwarf Boa (*Ungaliophis panamensis*), Isthmian Dwarf Boa (*U. continentalis*), Oaxacan Dwarf Boa (*Exiliboa placata*), and Eyelash Boas (*Trachyboa gularis, T. boulengeri*). There is one Cuban Dwarf Boa (*Tropidophis melanurus*) at the Wroclaw Zoo and one Haitian Dwarf Boa (*T. haetianus*) at St. Louis Zoo as of Jan. 24, 2014; source = ZIMS (ISIS). The AZA Snake TAG's regional collection plan is from 2010 so I am figuring those numbers are out of date.

Round Island Splitjaw Snakes

For many years, these two snakes (*Casarea* and *Bolyeria*) were considered to be members of the Boidae, perhaps due to similarity of head shape to *Candoia*, but their odd jaw was so unusual that scientists felt that both should be in their own family, Bolyeriidae. Despite listing in its own family, the splitjaw snakes are commonly known in the vernacular as "boas" and are listed as such in The Reptile Database <http://www.reptile-database.org/>. These taxa have an upper jaw bone split into front and back halves that are hinged together at a point just below the eye. Bloxam (1984), Waugh (1988), and Bloxam and Tonge (1986, 1988) reported on the captive management and reproduction of the endangered Round Island Splitjaw Snake (*Casarea dussumieri;* Fig. 14) at Jersey Wildlife Preservation Trust in Channel Islands. Their program included a plan to eradicate the introduced mammals and to restore native vegetation. In 1840, rabbits and goats were released on the island, resulting in damage to the vegetation; this caused soil erosion on the volcanic slopes and deterioration of palm forest habitat. Between 1977–1982, the Trust received a group of 11 snakes on loan from the Mauritian government to establish a captive-breeding program. Although feeding predominately on the Round Island Skink (*Leiolopisma telfairii*), Bojer's Skink (*Gongylomorphus bojerii*), Ornate Day Gecko (*Phelsuma ornata*), and Round Island Gecko (*Phelsuma guentheri*) in the wild, these snakes accepted mice in captivity, unusual since the Mauritian terrestrial vertebrate fauna lacked mammals until introduction of Black Rats (*Rattus rattus*). McAlpine (1981) followed activity patterns of six *Casarea* at the Trust and found that the snakes were primarily nocturnal but occasionally active during the day; the snakes are largely a terrestrial, sit-and-wait, vision oriented predator. Cundall and Irish (1986, 1989) described the function of the intramaxillary joint by analyzing snakes from the Trust colony. They believed that the unusual jaw morphology is an adaptation to subdue slippery or soft-bodied lizard prey. Clutch sizes ranged from 3–11 eggs; neonates averaged ca. seven inches in length (Bloxam 1984; Bloxam and Tonge 1988). We received some adults from the Trust at Dallas Zoo but the reptiles proved to be diffident feeders; Quentin Bloxam told me to stop regularly cleaning the cages and the snakes began feeding immediately (see Chiszar et al. 1980; Wellborn et al. 1982). Bloxam (pers. comm.) told me that the other species—Round Island Burrowing Splitjaw Snake (*Bolyeria multocarinata*)—has been extinct since 1975. His certainty was based on numerous trips to assess the existence of this species. The single individual he saw was identifiable by a scar.

Two Personal Anecdotes

I conclude this paper with two early experiences with boas and pythons that helped determine my life and fate, thus contributing to a financially modest career in the zoo profession.

When I began my less than stellar undergraduate career at Xavier University in Cincinnati, Ohio as a biology major in the late–1950s, I brought along a few snakes from home to keep me company. My plan was to prepare for a zoo career in herpetology so I asked for advice from the departmental chair. He wanted me to do neuroscience on chicks as a senior project, and that was of no interest to me; instead I insisted that my courses and project focus on living herps and include ethology, ecology, physiology, and herpetology. I did offer to use his chicks to feed my snakes. He countered by saying that my life would be nothing more than cleaning cages and aquariums *ad infinitum*—certainly prophetic as it turned out. My dormitory was large and rooms were spacious so there was plenty of room for my Boa Constrictor and Indian Python, each about seven feet (2.1 m) in length. The rooms were constructed of painted concrete block and the door frame was metal. One late evening after a night of debauchery at a local pub, my roommate and I returned to find the door frame and wooden door lying in the hallway surrounded by small chunks of block and concrete dust. We were certain that we had been burglarized but could find nothing missing. The next day, fellow students explained that a new custodian, allegedly a dipsomaniac sipping more than a few pints daily in the broom closet, had entered the room to clean, not knowing that snakes were there as well. When these unexpected inhabitants were sighted, he crashed through the closed door, knocking door and frame into the hallway and landing on top of the door. It was truly an example of superhuman strength, likely fueled with alcohol and reinforced with ophiophobia. He was never seen again. As word spread quickly through the university that I had snakes, our room was packed each week with onlookers to watch the snakes feed. It became obvious that a larger venue was needed. The proctor arranged to have the feeding demonstrations in the enormous common room so hundreds of students, many standing on the couches, could watch the show. Feeding times were published in the school newspaper. A few years ago, I opened my alumni magazine and found that my snake feeding was listed as one of the most memorable events in the history of the university and there was even a picture of a Boa Constrictor.

When one gives talks on snakes to the public, there is usually a predictable response and it is negative—ophidians crawl silently with darting tongue, and are frightening, mute, unblinking, height-challenged, ugly, scary, slimy, unpredictable, and so on, and many attendees are reluctant to touch them (see Burghardt et al. 2009). Dave Barker raised a tame Burmese Python which grew to an impressive size at Dallas Zoo and we used it for presentations. The animal was named "Christian" and we transported him in a large trunk which was always closed on stage until the finale when the snake was introduced to the visitors. One day at a Dallas high school, the audience, numbering over 500 persons, was seated in a large auditorium with a steep sloping floor toward the front. When I finished my slide show, I opened the trunk and pulled out Christian. Primal screams emanated from the throng and a wave of humanity remindful of attacking Huns rushed toward the elevated stage, climbed up the front and sides, pushed me aside, knocked over the podium, microphone, speakers, table, and my props, and began grabbing and petting the snake—a near riot in my view. Envision the final game of the World Series in baseball where the winners are leaping over each other to celebrate victory. After many minutes, teachers and I finally calmed the crowd but the response was so unexpected that I was badly shaken; fortunately, Christian remained calm although the snake had every right to defend itself by biting potential threats. Later, the students sent apology notes (likely forced upon them by teachers) that were stunning—poorly written, grammatically incorrect with creative spelling and punctuation, and virtually incomprehensible—had I not been there, I would not have had a clue as to what had transpired.

Acknowledgments.—This contribution is dedicated to Richard A. Ross, the late Thomas A. Huff, Peter J. Tolson, David G. Barker, Tracy M. Barker, and Trooper Walsh, whose many writings have increased our understanding of the lives of boas and pythons.

I have benefitted from many discussions with Harry W. Greene and Gordon M. Burghardt about the value of zoo collections to advance scientific understanding and the importance of collaborations between academics and zoo workers. A poignant example using boas and pythons in zoos to increase sample size is their seminal paper (Greene and Burghardt 1978).

Lauren Augustine, Dave Barker, Judith Block, Peter Brazaitis, Matt Evans, William Lamar, Joe Mendelson, Matt Neff, Richard Ross, Steve Sarro, Peter Tolson, and Trooper Walsh reviewed early drafts. Thanks are due to Kraig Adler, Barry Armstrong, Ed Bronikowski, Kristen Bullard, Jonathan Campbell, Jeff Ettling, Elliott Jacobson, Alan Kardon, Karl Kranz, Jim Langhammer, Polly Lasker, Roy McDiarmid, Don Middaugh, Mandy Murphy, Benin Noble, Leslie Overstreet, Ivan Rehák, Kamuran Tepedelen, Daria Wingreen, William Xanten, and George Zug for various courtesies.

ART IN HERPETOLOGY

Snapping Turtle (*Chelydra serpentina*)
Matt Patterson — acrylic on vellum illustration board 14" x 42"

Matt Patterson grew up in a small town in New Hampshire, USA. His father was a high school biology teacher, and from an early age Matt was exposed to many different species of animals. As far back as he can remember, he has always had the same two interests: wildlife and art. Today he is a professional illustrator and his work reflects these these passions.

In 2003 Matt graduated from the University of New Hampshire with a BA in Studio Art. In 2006 he received a professional certificate in illustration from the Art Institute of Boston (AIB).

Since graduating in 2006 from AIB, Matt has completed projects ranging from scientific illustration used for posters and books to product illustration. His work has been exhibited nationally. Matt is also a member of the Guild of Natural Science Illustrators. The Common Snapping Turtle painting shown here is currently being exhibited in their members' show.

In 2009, Matt accepted his first contract to illustrate a book for the University Press of New England titled *Freshwater Fish of the Northeast*. This book contains a total of 61 species of freshwater fish. Matt enjoyed many fishing outings in order to gather references needed to complete the illustrations. The book was released in the spring of 2010 and won the National Outdoor Book Award the same year in the artistic merit category.

Matt works in a variety of different mediums ranging from wood carving to digital painting. However, his preferred medium and the majority of his work is completed using acrylic paints. His process first starts with gathering references and other pertinent information on the subjects. He then completes several rough sketches. Once he chooses a composition, he does a pencil drawing on illustration board. Matt works with washes initially and then builds up the layers of paint from thin to thick using acrylics. Often times, he tones the paper or illustration board he is using with coffee prior to painting. This tone gives the illustration a unique texture.

Currently, Matt is illustrating a book on reptiles and amphibians found in the Northeast of North America. Matt is excited about this project and looks forward to its completion.

For information on artwork or commissions, contact Matt at mpatter3@gmail.com or visit www.mpattersonart.com. Artwork is also available for sale at https://www.etsy.com/shop/StoneridgeArtStudios.

ABOUT OUR COVER: *Vipera aspis francisciredi*

Across its broad range in Western Europe, *Vipera aspis* displays variation in color pattern, often including some degree of sexual dichromatism—males are brightly marked with strongly contrasting patterns, while female colors tend to be more muted and well camouflaged. This phenomenon is not unusual among populations of some species of *Vipera*, but is otherwise rare among snakes. Color differences between the sexes are amplified during the breeding season, and likely reflect different selection pressures on wide-ranging males versus sedentary females (Shine and Madsen 1994. Journal of Herpetology 28[1]:114–117).

Vipera aspis francisciredi (Redi's Viper) is one of several distinctive forms of *V. aspis*. This subspecies, which occurs in central and northern Italy and extreme southern Switzerland, also exhibits sexual dichromatism. Additionally, snakes from higher elevation populations, such as in the central Apennines of Italy, may be melanistic, a trait that likely confers thermoregulatory benefit (Castella et al. 2013. Journal of Zoology 290:273–280).

Despite documentation of morphological and genetic diversity across the extensive range of *V. aspis*, recent analyses do not appear to fully support elevating the subspecies to full species, and for the time being the traditional view of a single, polytypic species is retained (Zuffi et al. 2002. Amphibia-Reptilia 23:191–213; Ursenbacher et al. 2006. Molecular Phylogenetics and Evolution 38:546–552; Golay et al. 2008. Amphibia-Reptilia 29:71–83).

Redi's Viper is considered Endangered as a result of habitat loss related to agriculture and other human practices that alter native landscapes (Monney and Meyer 2005. Rote Liste der gefährdeten Reptilien der Schweiz. BUWAL-Reihe: Vollzug Umwelt, 50 S. [BUWAL, Bern, Switzerland]).

The adult male Redi's Viper on our cover was photographed by **Matteo Di Nicola**. This "wide-angle macro" image was recorded using a Nikon D300 camera and a Tokina 10–17mm lens (f/22, ISO 400, 1/100 sec shutter speed, focal length 10mm), with fill flash provided by a Nikon R1 wireless dual flash system. The snake was encountered on stony ground near a birch forest in Ticino, Switzerland at the northern end of this subspecies' range. Residing in northern Italy, Di Nicola notes that despite the fact that Italy offers an enormous variety of nearby easily accessible habitats, the region is densely populated and it is almost impossible to find areas untouched by human activities. For that reason, many Italian wildlife photographers have been forced to look for their photographic subjects abroad as "wild specimens here are frustratingly wary of man and close to unapproachable." Additional images by Di Nicola may be viewed at www.matteodinicola.com.

Editor's note.—Thanks to Louis Porras and Gordon Schuett for editorial assistance.

SSAR BUSINESS

SSAR Roger Conant Grants-in-Herpetology Award Winners for 2014

An award in the amount of US $500 was made to each of the following individuals:

Conservation.—**Javan Bauder**, University of Massachusetts, "Conservation Genetics of the Federally Threatened Eastern Indigo Snake (*Drymarchon couperi*) in Central Florida." Advisor: Kevin McGarigal. **Bailey Patillo**, University of Memphis, "Salamander Susceptibility and Response to the Amphibian Fungal Pathogen *Batrachochytrium dendrobatidis*." Advisor: Matthew Parris

Education.—**David Steen**, Alabama Natural Heritage Program at Auburn University, "Living Alongside Wildlife: An Online Resource for Amphibian and Reptiles Outreach and Conservation."

The Andrew H. Price Field Research Grant In Herpetology.—**Brian Folt**, Auburn University, "Does Leaf-drop Phenology Regulate Abundance Cycles of Terrestrial Amphibians and Reptiles in Wet Neotropical Forests?" Advisor: Craig Guyer. **Scott Travers**, University of Kansas, "Adaptive Radiation and Community Assembly of Ceratobatrachid Frogs in the Solomon Islands." Advisor: Rafe Brown

Laboratory Research.—**Andrew Frank**, University of Connecticut, "Testing the Parallel Speciation Hypothesis in Western North American Skinks (*Plestiodon*)." Advisor: Elizabeth Jockusch. **Sofia Prado-Irwin**, San Francisco State University, "Disease Dynamics of the Fungal Pathogen *Batrachochytrium dendrobatidis* in the California Salamander *Ensatina eschscholtzii*." Advisor: Andrew Zink

Travel.—**Christopher Akcali**, University of North Carolina-Chapel Hill, "The Role of Batesian Mimicry in Divergence and Speciation." Advisor: David Pfennig. **Brenna Forester**, Duke University, "Evaluating the Implications of Local Adaptation, Habitat Connectivity, and Gene Flow for Terrestrial Salamanders Under Global Change." Advisor: Dean Urban

International.—**Nina Seren,** CIBIO Institute (Portugal), "Genetic Response to Heavy Metal Exposure in Amphibian Larvae Under Laboratory Experimental Conditions." Advisor: Ylenia Chiari**. Marta Vidal-Garcia**, The Australian National University, "Unraveling Body Shape Evolution in Australo-Papuan Myobatrachid Frogs." Advisor: J. Scott Keogh

Undergraduate Research.—**Renae Reed**, Peninsula College, "Quantifying an Active Population of Central America's Rarest Turtle, *K. angustipons*." Advisor: Brian Hauge

SSAR thanks Committee Chair, Joshua M. Kapfer (University of Wisconsin-Whitewater), and the following reviewers for their service: David Blackburn (California Academy of Sciences), Ben Cash (University of Central Arkansas), Rebecca Christoffel (Iowa State University, Matthew Fujita (University of Texas-Arlington), Katy Greenwald (Eastern Michigan University), Toby Hibbitts (Texas A&M University), Joe Milanovich (Loyola University), Joanne Ocock (University of South Wales, Australia), Kevin Russell (University of Wisconsin-Stevens Point), Jennifer Sheridan (North Carolina Museum of Natural Sciences), William Sutton (Tennessee State University), Jessica Wooten (University of Findlay, Ohio).

Details concerning the Roger Conant Grants-in-Herpetology program for 2015 can be found in *Herpetological Review* 45:382–383.

Catalogue of American Amphibians and Reptiles Now Open Access

The *Catalogue of American Amphibians and Reptiles* (CAAR) was initiated in 1963 with funding from the National Science Foundation under the auspices of the American Society of Ichthyologists and Herpetologists. The first editor was William J. Riemer. SSAR took over the series in 1971. Over the four-plus decades of its existence, many editors and section editors have overseen the production of hundreds of accounts of Western Hemisphere amphibians and reptiles. As then-Editor Jaime Villa noted in the Foreword to the Index for Accounts 1–400 (published in 1988), the *Catalogue* "represents one of the most important long term cooperative activities undertaken by the American herpetological community and is expected to remain a primary resource for the taxa covered long into the future." Twenty-seven years later that statement still holds. Along the way, the accounts have incorporated improved graphics and full color illustrations of the focal species. The first accounts under new editors Christopher J. Bell and Travis J. LaDuc have just been issued, covering *Graptemys gibbonsi* (Pascagoula Map Turtle), *Anolis smaragdinus* (Bahamian Green Anole), and *Cubophis vudii* (Bahamian Racer). As a service to the herpetological community, SSAR has made the entire series Open Access. Accounts 1–903 may be accessed online at <www.ssarcaar.com>.

NEWSNOTES

Mayr Award Goes to Rayna Bell

PHOTO BY ANDREW STANBRIDGE

The Ernst Mayr Award is given to the presenter of the outstanding student talk in the field of systematics at the annual meetings of the Society of Systematic Biologists (SSB). This is SSB's premier award, and is judged by the quality and creativity of the research completed over the course of the student's Ph.D. program. The 2014 winner of the Mayr Award is **Rayna Bell** of Cornell University. Bell recently completed her PhD under the direction of Kelly Zamudio, and is moving on to a post-doctoral position in the University of California system. Bell's paper, coauthored with Robert Drewes and Kelly Zamudio, was titled: "Comparative population genomics of island endemic reedfrogs: dispersal and diversification in the Gulf of Guinea."

Herpetologists have been especially well represented in the list of Mayr Award winners since the program's inception in 1976. Fully 28% of the award winners to date, which include botanists as well as zoologists of all disciplines, have been herpetologists. Previous winners include Matt Brandley, David Cannatella, Richard Cloutier, Kevin de Queiroz, Linda Ford, Darrel Frost, Anna Graybeal, Adam Leaché, Jim McGuire, Steve Poe, Dan Rabosky, and Jon Richmond.

Reptile Database Update

PHOTO BY TRUONG NGUYEN

FIG. 1. *Cyrtodactylus vilaphongi*, recently described by Schneider et al. (2014. Zootaxa 3835[1]:080–096), from Luang Prabang Province, Laos, is the 10,000th species to be listed in the Reptile Database.

As of 1 August 2014, the Reptile Database (http://www.reptile-database.org) now contains more than 10,000 reptile species. The 10,000th entry is *Cyrtodactylus vilaphongi* Schneider et al., 2014 from Laos (Fig. 1). More precisely, the database now lists 10,038 species (including 79 described this year), up from 9952 in April 2014 (refer to *HR* 45:385). There are now 34,104 references (including 698 published this year), up from 33,558 in April.

Selected Taxonomic News and Changes

New country checklists.—The country checklists for several countries have been updated, namely for Namibia (Herrmann and Branch 2013. J. Arid Environments 93:94–115), Uruguay (Carreira et al. 2012. Bol. Soc. Zool. Uruguay 21:9–29), and Nepal (Kästle et al. 2013. Field Guide to Amphibians and Reptiles of Nepal. ARCO-Nepal).

Agamidae.—All species are now mapped to subfamilies (with help from Philip Wagner and Ulrich Manthey).

Gerrhosauridae.—Now following Bates et al. 2013, including two new genera, *Broadleysaurus* Bates & Tolley gen. nov., and *Matobosaurus* Bates & Tolley gen. nov.

Gekkonidae.—New genera: *Kolekanos* Heinicke et al. 2014, and *Ramigekko* Heinicke et al. 2014.

Gymnophthalmidae.—Now all species mapped to subfamilies (with help from Tiffany Doan).

Turtles.—Now following the turtle checklist by TTWG 2014 (which now has maps, too!).

Typhlopidae.—After Hedges et al. 2014 recently proposed several new genera and other taxonomic changes, many of them have been reverted and otherwise changed by Pyron and Wallach 2014, who also proposed a new genus, *Lemuriatyphlops*.

The Splitting Continues.—Several species groups have been split up, including but not limited to *Pelomedusa subrufa* (now 10 species), *Blanus, Crotalus triseriatus*,, and others.

Global checklist.—An updated global checklist of all reptiles with their higher taxa is now available as an Excel spreadsheet at http://www.reptile-database.org/data/

Please send corrections and additions via the contact link inside the species accounts.

David J. Morafka Memorial Research Awards 2015

In honor and memory of Prof. David J. Morafka, distinguished herpetologist and authority on North American gopher tortoises, the Desert Tortoise Council, with the aid of several donors, has established a monetary award to help support research that contributes to the understanding, management and conservation of tortoises of the genus *Gopherus* in the southwestern United States and Mexico: *G. agassizii, G. morafkai, G. berlandieri*, and *G. flavomarginatus*.

Award Amount: US $2,000 to be awarded at the Desert Tortoise Council's Annual Symposium, depending on the availability of funding and an appropriate recipient.

Eligibility: Applicants must be associated with a recognized institution (e.g., university, museum, government agency, non-governmental organization) and may be graduate students, post-doctoral students, or other researchers. They must agree to present a report on the results of the research in which award funds were used at a future symposium of the Desert Tortoise Council.

Evaluation Criteria: Applications will be evaluated on the basis of the potential of the research to contribute to the biological knowledge of one or more of the above gopher tortoise species, and to their management and conservation. Important considerations are the significance and originality of the research problem, design of sampling and analysis, preliminary data supporting the feasibility of the research, and the likelihood of successful completion and publication.

Application Procedure:

1. Download and open an application form from the Desert Tortoise Council's website www.deserttortoise.org. The form is electronically interactive.

2. Provide all information requested on the application, including a description of the research project in no more than 1200 words.

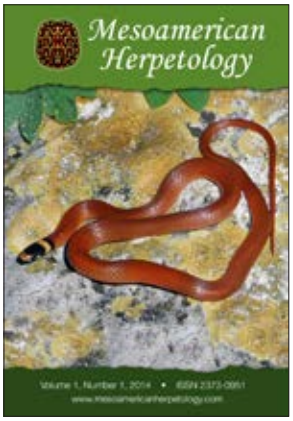
3. Submit the completed application to grstewart@csupomona.edu as a pdf document.

4. Applications must be supported by the applicant's CV and three letters of recommendation, one of which must be from the applicant's research advisor, supervisor, or a knowledgeable colleague. Instruct the recommenders to submit their letters to grstewart@csupomona.edu as pdf documents.

5. All application materials and letters of recommendation must be received by **1 December 2014**. They will be evaluated by a committee of gopher tortoise biologists appointed by the Desert Tortoise Council Board of Directors.

6. The research award recipient will be notified of his/her selection by **19 January 2015** and the award will be presented at the 2015 Desert Tortoise Council Symposium, 20–22 February 2015.

ZenScientist Grant Recipient Named



Walter Paulin Tapondjou Nkonmeneck is the recipient of the first ZenScientist Grant. The grant was administered by the Herpetological Association of Africa (HAA) with money donated by ZenScientist.com. Walter will be receiving US $500 for his project titled: "Endemic chameleons of the Cameroon volcanic line: Morphological variation, intra and interspecific gene flow and influence of anthropogenic activities on habitat selection, perch height and feeding ecology." Walter is a Ph.D. candidate studying under Dr. Krystal A. Tolley.

The remaining $250 has been sent to HAA to offer as poster or presentation awards at their annual meeting to be held at the Gogabeb Research & Training Centre, Namibia, 20–22 November 2014. (see: https://sites.google.com/site/12haagobabeb/).

Additionally, Breck Bartholomew and ZenScientist.com will be sending a copy of the classic *The Lizards of South Africa* by V. F. FitzSimons, along with a few smaller publications on African herpetology, to the HAA to auction or use as prizes at the meeting.

The purpose of the ZenScientist Grant is to promote herpetological research by herpetologists who may not have other funding available. The grant will be administered by one of the smaller herpetological societies associated with ZenScientist.com and that typically does not have other funding to offer grants to its members. Persons wishing to contribute to this program may do so online at: http://www.zenscientist.com/index.php/subscriptions-1002

New Journal for Middle American Herpetology

Mesoamerican Herpetology is a peer-reviewed, open-access, electronic journal dedicated to the study of the herpetofauna of Mexico and Central America. Its purpose is to (1) promote herpetological research throughout the region, (2) provide an outlet for the publication of noteworthy papers and notes, and (3) develop a greater level of interaction among biologists, students, conservationists, and other interested parties throughout the region.

Manuscripts on a wide variety of herpetological topics will be considered, including those on taxonomy, systematics, phylogeography, biogeography, conservation, evolution, life history, ecology, behavior, diet, reproductive biology, physiology, diseases, venoms, field studies, techniques, and herpetoculture. Submissions must represent a significant contribution to the field of herpetology for consideration in the journal.

To learn more about the new journal and how to submit manuscripts, please visit http://www.mesoamericanherpetology.com/.

Amphibian & Reptile Conservation

Amphibian & Reptile Conservation (ARC) is an open-access international journal (ISSN: 1083-446X; eISSN: 1525-9153) published twice per year. ARC publishes original peer-reviewed research, reviews, short communications, new species descriptions, country overviews, and more, focusing on a variety of topics relating to the biology, conservation, natural history, and diversity of the world's amphibians and reptiles.

ARC News Alerts provide news and information, including notifications when papers are published online. To subscribe to these brief alerts, visit http://amphibian-reptile-conservation.org/subscribe.html

For a full list of recent papers, as well content planned for future issues, visit the ARC webpage: amphibian-reptile-conservation.org

Smithsonian Herpetological Information Services Publications

The Division of Amphibians and Reptiles of the National Museum of Natural History continues to publish SHIS on an irregular basis. The SHIS series began in 1965 as a "publication" to increase access to indices, translations, bibliographies, and similar materials, which are not published as part of a research project, yet are potentially useful to other herpetologists. We continue this tradition and invite contributions from herpetologists who have developed such materials. If you have such contributions, please contact George Zug [zugg@si.edu] for details of submission.

The more recent ones, 2000 and forward, are:

123 Herpetofauna of Estado Falcón, Venezuela: a checklist with geographical and ecological data. Abraham Mijares-Urrutia & Alexis Arends R. 2000.

MEETINGS

Meeting announcement information should be sent directly to the Editor (herpreview@gmail.com) well in advance of the event. We also welcome brief reports of meetings; please consult the Editor for details.

30 September–4 October 2014 — XIII Iberian Congress of Herpetology, Universidade de Aveiro, Aveiro, Portugal. Information: http://herpe2014.biologiaatua.net/

1–5 October 2014 — 50th Annual Meeting of the German Society for Herpetology and Herpetoculture (DGHT), Bonn, Germany. Information: www.dght.de

10–13 October 2014 — 4th Biology of the Vipers Conference, Athens, Greece. Information: http://www.elerpe.org/viperconf.html

16–18 October 2014 — 36th Annual Gopher Tortoise Council Meeting, Albany, Georgia, USA. Information: www.gophertortoisecouncil.org/annual-meeting

19–23 November 2014 — Herpetological Association of Africa 2014 Conference, Gobabeb Research & Training Centre, Namib Desert. Information: http://www.africanherpetology.org/

20–22 February 2015—Desert Tortoise Council Symposium, Las Vegas, Nevada, USA. Information: http://www.deserttortoise.org/symposium/

2–5 April 2015 — 62nd Annual Meeting of the Southwestern Association of Naturalists, San Diego, California, USA. Information: http://www.biosurvey.ou.edu/swan/annualm.html

15–19 July 2015 — American Society of Ichthyologists and Herpetologists and The Herpetologists' League annual meeting, Reno, Nevada, USA. Information: www.asih.org

30 July–3 August 2015 — 58th Annual Meeting of the Society for the Study of Amphibians and Reptiles (with Partners in Amphibian and Reptile Conservation, Kansas Herpetological Society, and International Society for the History and Bibliography of Herpetology), Lawrence, Kansas, USA.

CURRENT RESEARCH

The purpose of Current Research is to present brief summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editors, Beck Wehrle or Ben Lowe; e-mail addresses may be found on the inside front cover.

Testing an Adaptive Hypothesis for Temperature-Dependent Sex Determination

Temperature-dependent sex determination (TSD) has potential costs such as skewed sex ratios with slight climatic shifts. Nevertheless, TSD is widespread among reptiles, suggesting an adaptive basis. An experimental study employing a short-lived agamid lizard showed TSD is advantageous when the sexes develop best at different incubation temperatures. However, demonstrating this in long-lived taxa such as tuataras, crocodilians, and turtles where lifetime fitness is difficult to assess has proven difficult. Noting that many TSD turtle species overwinter as hatchlings in the nest, the authors of this paper conducted an experiment aimed at determining how overwintering temperature affects Painted Turtle (Emydidae: *Chrysemys picta*) hatchlings. *C. picta* is a TSD species: warmer *C. picta* nests produce females and cooler nests produce males, and female nests are also warmer in winter than male nests, with male nests more frequently dipping below freezing. Forty post-hatching nests were dug up in September and the hatchlings were brought into the lab; nests were chosen based on field temperatures with the goal of having a mix of male dominant, female dominant and mixed sex nests. From each nest, two hatchlings were euthanized and their yolk and body mass were measured; the rest were measured and divided between two treatments: warm and cool overwintering temperatures, representing typical female and male nests, respectively. Over the winter, hatchlings were subjected to closed-system respirometry to measure their metabolic activity. At the end of the experiment, the hatchlings were euthanized, and their length and yolk and body masses were recorded. These experiments revealed that cool-treatment males grew more, respired less, and used less yolk than males in the warm treatment and females in the cool treatment. Conversely, females in the warm treatment used less yolk and grew more than cool-treatment females and warm-treatment males, and all females respired less than warm-treatment males. These trends held regardless of whether the turtles were from single- or mixed-sex nests, however, cool-treatment males from single-sex nests used less yolk, grew more, and respired less than their mixed sex counterparts, and warm-treatment females similarly outperformed mixed nest females. These experiments clearly show in *C. picta* that the temperatures that produce each sex provide the optimal overwintering conditions for each sex, supporting an adaptive basis of TSD in this species.

Female Tree Lizard Mate Preference Differs Between Morphs

Several studies have investigated the male behavioral syndromes associated with different throat-color morphs in various lizards of the family Phrynosomatidae; however, little attention has been paid to species with multiple female morphs. To determine if mate preference differences are associated with different female morphs, the authors of this study performed laboratory-based mate choice experiments with Tree Lizards (*Urosaurus ornatus*), a species where females either possess a yellow or orange throat. In this species, males bear blue, yellow, or orange throats, which have been associated with aggressive-territorial, peripheral, and roaming strategies, respectively. Prior to the experiments, in addition to throat color, males were evaluated for their chest patch (size, color intensity) and body condition (mass relative to snout-vent length), none of which were found to be correlated with throat color but may influence female mate choice. The experimental design consisted of a central container for the female flanked by two containers for males (opposite each other). In each trial, males of different throat colors were added to the flanking containers, and the position of the female was scored every half hour over eight hours, with proximity to a male being construed as preference. In these experiments, the authors demonstrated that when presented with a yellow- and an orange-throated male, both female morphs preferred the yellow male, with the orange-throated female also showing preference for males with a large chest patch. In the blue/orange and blue/yellow male trials, females showed no significant preference for either male morph. However, in the blue/orange trials, yellow-throated females showed a preference for males with small chest patches, and both female morphs spent more time near orange-throated males than they did in the yellow/orange trials. The authors posit that the yellow females' preference for small patch size in the blue/orange trials may indicate they are choosing less aggressive males to avoid injury. No preferences for chest patch color intensity or body condition were found. As these lizards may be utilizing olfactory in addition to visual cues, the authors also conducted a series of similar experiments where females were allowed to choose between femoral pore secretions from males of two morphs. In these experiments, the only significant preference was yellow-throated females for yellow-throated males. However, the results of the two experiments were similar (i.e., not significantly different), indicating that visual and olfactory modalities may carry redundant information used in females choice.

Genetic Connectivity Despite Anthropogenic Habitat Alterations in Tiger Salamanders

Pond-breeding amphibians have limited options when it comes to oviposition sites, and are often dispersal-limited as well. Therefore, anthropogenic changes at the landscape level have a high potential of disrupting gene flow among amphibian populations. The authors of this paper set out to discover whether gene flow disruption can be discerned within relictual distributions of Tiger Salamanders (*Ambystoma tigrinum*) in the anthropogenically altered Mid-Atlantic region (USA). They collected non-destructive tissue samples from 26 ponds in two regions of *A. tigrinum* persistence: eastern Long Island (New York), and the southern tip of New Jersey. Using these samples, the authors sequenced 12 microsatellite markers and subjected the recovered genotypes to analyses developed to identify the best estimate of the number of metapopulations (STRUCTURE), the results of which were included in an analysis of molecular variance (AMOVA) analysis to establish which levels the observed genetic variation can be attributed to (within ponds, within metapopulations, etc.). These genotypic data were also used to calculate pond effective population sizes, and pairwise F_{ST} values for every pair of ponds within the two regions. Using GIS software, landcover data layers, and understanding of *A. tigrinum* habitat suitability, the authors calculated "surface resistance" distances between ponds. These surface resistance distances represent a realistic distance a salamander would have to travel to disperse from one given pond to another. Using these surface resistance distances as well as straight-line distances, the authors conducted Mantel tests to see if the pairwise F_{ST} values were significantly correlated with either of the geographic distances. This research revealed the best estimate of the number of metapopulations to be three: the New Jersey samples, two of the Long Island ponds, and the remainder of the Long Island ponds. The AMOVA analysis found very little of the genetic structure can be attributed to being among ponds, indicating between-pond but within-metapopulation gene flow is relatively high. Finally, neither straight-line nor surface resistance distances were correlated with genetic structure in any of the regions or metapopulations, further demonstrating significant gene flow. Nevertheless, estimates of pond effective population sizes were very low, ranging from 5 to 44, and overall genetic diversity was low, revealing that despite inter-pond gene flow, these salamanders are still likely threated by population decline and habitat destruction.

Titus, V. R., R. C. Bell, C. G. Becker, and K. R. Zamudio. 2014. Connectivity and gene flow among eastern tiger salamander (*Ambystoma tigrinum*) populations in highly modified anthropogenic landscapes. Conservation Genetics (*in press*) doi:10.1007/s10592-014-0629-5.

Effects of Warming and Drying on Development Investigated in Three Anuran Species

Climate change is expected to frequently affect a single species in multiple ways at the same time. Such is the case in western Canada, where temperature increases are predicted to coincide with reduced water availability. Unfortunately, the combined effect of these factors on individual species is largely unknown. The authors of this study teased apart the effects of increased temperature and evaporation on amphibian development in a full-factorial mesocosm experiment. Tadpoles of three western Canadian species, Northern Red-legged Frog (*Rana aurora*), Pacific Chorus Frog (*Pseudacris regilla*), and Great Basin Spadefoot (*Spea intermontana*), were divided among cattle tanks and subjected to the following treatments: ambient temperature (control), ~3°C increased temperature, "increased drying" (implemented via water removal), and a combined temperature and drying increase treatment. The tanks were initially filled with tap water and supplemented with pond water, dried leaf litter, plankton, phosphorus, and nitrogen. A mesh was applied to the top of the tank to prevent colonization by larger animals while allowing rain and small arthropods in. Temperature and water depth were measured regularly, and tadpoles were measured on day 31 and again when they metamorphosed or their pond dried to determine rates of growth. Density of periphyton (microscopic organisms occurring on surfaces and serving as tadpole food) was measured twice over the experiment. To analyze these data, the authors used linear mixed-effects modelling to evaluate the effects of warming, drying, and species on four response variables: growth to day 31, size and mass at metamorphosis, and time to metamorphosis. Similarly, generalized linear modelling was performed to evaluate the effect of these three explanatory variables on percentage of tadpoles surviving to metamorphosis and periphyton availability.

Over the experiment, the tanks in the increased drying group completely dried, those experiencing warming dried faster, and the increased drying tanks were warmer than their "permanent" controls. Tadpoles in warmed tanks grew faster, but metamorphosed much earlier, resulting in a smaller-at-metamorphosis trend (only significant in *S. intermontana*). Despite this, *P. regilla* and *S. intermontana* in warming treatments were more likely to survive to metamorphosis than their control counterparts, possibly explained in part by increased periphyton availability. In the drying treatments, *R. aurora* and *S. intermontana* metamorphosed significantly earlier (while only the latter grew faster and was more likely to survive to metamorphosis) and *P. regilla* and *S. intermontana* both metamorphosed at a significantly smaller size. The authors explored the two-way interactions of the explanatory variables, and determined that all interactions were additive or antagonistic (combined effects were less than the sum of the individual effects). For instance, though warming and drying both tended to increase growth rate and chance of surviving to metamorphosis, tadpoles in treatments experiencing both warming and drying grew slower and survived less frequently than expected if the effects were additive. The effects of warming and drying on metamorphosis timing and size were found to be nearly additive. These results indicate *S. intermontana* is the most developmentally flexible of the three. This study highlights the importance of evaluating multiple stressors simultaneously in studies attempting to determine risks to species, as combined effects may not be additive.

Basis of Paedomorphism Revealed in *Eurycea tynerensis*

The biological underpinnings of metamorphosis in amphibians have long been of scientific interest. Researchers have demonstrated that thyroid hormones (TH) are required for metamorphosis; specifically, they combine with thyroid hormone receptor proteins (TRP) to upregulate the transcription of proteins necessary for metamorphosis, including additional TRP. Though it is clear this pathway is important in paedomorphism, how it is altered to achieve this phenomenon is complicated, as the application of TH instigates metamorphosis in some paedomorphic species (e.g., the Axolotl) but not in others (e.g., *Necturus*). To shed more light on this question, the authors of this study examined the effects of TH on larval *Eurycea tynerensis*, a plethodontid species that is comprised of paedomorphic and metamorphic populations. Larval salamanders were collected from two metamorphosing populations and two paedomorphic populations. These four groups of salamanders were each divided into control and TH exposure treatments. After 48 hours, a piece of the tail fin was removed from each salamander and subjected to RNA extraction. From this, a cDNA library was made and sequenced for three transcripts: two TRP isoforms and a third transcript not involved with metamorphosis (as a standard). Additionally, the cDNA libraries underwent expression analysis, where each of the three transcripts were quantified using a qPCR machine. After 21 days, the animals were euthanized, cleared, and stained, allowing evaluation of the degree to which the epibranchial cartilages had metamorphosed into the adult condition. These experiments revealed that TH exposure dramatically elevates TRP levels in metamorphosing populations relative to paedomorphic populations and controls. Paedomorphic salamanders exposed to TH did show an increase in TRP concentration over controls, however these increases were not generally significant. One paedomorphic population exhibited low TRP concentrations overall; interestingly, previous work demonstrated that this population diverged from metamorphosing *E. tynerensis* earlier than did the other paedomorphic population, indicating the possibility of a phylogenetic effect with regard to TH response. The examination of the epibranchials revealed TH exposure caused nearly complete metamorphosis in the metamorphosing salamanders, while the epibranchials of the paedomorphic and control salamanders underwent little or no remodeling. Again, the early-diverging paedomorphic population showed no effects from the TH. This study demonstrates that reduced tissue sensitivity to TH, and not reduced TH production (sensu *Ambystoma*), is underlying paedomorphism in at least this *Eurycea* species.

Young Skinks Capable of Social Learning

Recent studies have greatly expanded the taxonomic breadth of social learning beyond birds and primates. For instance, tortoises have recently been shown they can learn to navigate obstacles by watching other tortoises. As squamates have never been evaluated for social learning, the authors of this paper subjected Eastern Water Skinks (*Eulamprus quoyii*) to two social learning experiments. In the first, skinks of two age classes (young and old) were assessed for their ability to learn to lift a yellow lid to access a mealworm beneath. Half the skinks in each age class were allowed to observe another skink repeatedly accomplish the task for an hour (social learning treatment), while the other half simply witnessed another skink move around its enclosure for an hour (control). Subsequently, the observer lizards were given 16 opportunities to accomplish the task, and were considered to have learned the task once they accomplished it in five of six consecutive attempts. In the second experiment, the same skinks were tested for their ability to learn that when presented with a blue and a white cap, a mealworm is accessible beneath the blue but not beneath the white. A successful attempt entailed the skink choosing to lift the blue cap first, and they were given 24 tries overall; otherwise the experimental design and learning criteria were identical to that of the first experiment. The authors used generalized linear and generalized linear mixed models to analyze the data. Neither age class nor social learning opportunity significantly affected a skink's probability of learning either experiment's task. However, in the second experiment there was a significant age class × social learning interaction, where young skinks provided a social learning opportunity learned the task faster than old and control skinks. Young skinks in the social learning treatment were also more likely to learn the task from the beginning and never choose a white lid, and to choose the blue lid on the first trial, than old or control skinks. Old, social-learning-treatment lizards showed no performance improvements over their control counterparts. This study demonstrates that in some circumstances young *E. quoyii* can benefit by observing conspecifics, which is surprising as they are not considered particularly social lizards. Furthermore, this social learning ability appears to diminish with age. Certainly, more social learning studies incorporating snakes and lizards are needed.

Noble, D. W. A., R. W. Byrne, and M. J. Whiting. 2014. Age-dependent social learning in a lizard. Biology Letters 10:20140430.

Reptiles and Amphibians of Australia

Seventh Edition

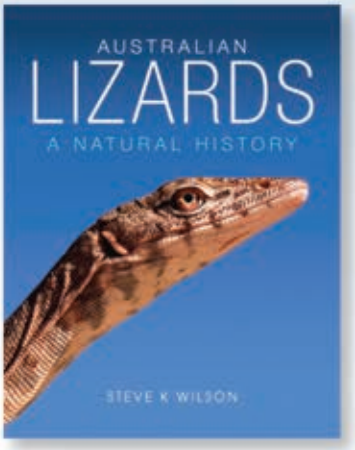
Harold G. Cogger

1036 pp, maps, color illus & photos throughout
Cloth, $148.95

CSIRO PUBLISHING

This classic work, originally published in 1975, has been completely brought up to date. This seventh edition includes all species described prior to October 2013. *Reptiles and Amphibians of Australia* is a complete guide to Australia's rich and varied herpetofauna, including frogs, crocodiles, turtles, tortoises, lizards and snakes.

For each of the 1,194 species there is a description of its appearance, distribution and habits. Each species is accompanied by a distribution map and, in most cases, a color photograph of the living animal.



The book includes 130 simple-to-use dichotomous keys that in most cases allow a specimen in hand to be identified. In addition, it has a comprehensive list of scientific references for those wishing to conduct more in-depth research, an extensive glossary, and basic guides to the collection, preservation and captive care of specimens.

- World-renowned author and work
- Comprehensive, up-to-date account of all reptiles and amphibians in Australia
- Only book to include identification keys to all Australian reptiles and amphibians
- Large photographs, useful for identification
- Maps of Australia-wide patterns of species richness in frogs, lizards and snakes

Second Update

University of Kansas Meeting in 2015

Society for the Study of Amphibians and Reptiles

co-sponsored by Partners in Amphibian and Reptile Conservation (PARC)

together with the herpetological societies of Kansas, Missouri, and Arkansas, the Center for North American Herpetology, *and the* International Society for the History and Bibliography of Herpetology

Symposium

Bones, Frogs, & Evolution

Organized by David Blackburn, Anne Maglia, and David Cannatella

This event, kept strictly confidential until now, will celebrate the exceptionally productive career of Linda Trueb, Curator Emerita, KU Herpetology Division. The contributions of Trueb's students, spanning 40 years of scholarship, will include oral presentations from many of her highly successful doctoral mentees. Invited participants include Ana Baez, David Blackburn, David Cannatella, Luis Coloma, Helio da Silva, Eli Greenbaum, Anne Maglia, Dave McLeod, Greg Pregill, Chris Sheil, Erik Wild, and William Duellman.

Projected Costs for 2015

- *Registration fees (member rates):*
  - Students . . . . . US $150
  - Regular $295
  - Seniors, retired / over 70 . . . . . $150
- *Dorm room rates (on campus, linens included):*
  - Dual-occupancy rooms or suites, per day . . . . . starting at $35
  - Single-occupancy rooms or suites, per day . . . . . starting at $55

There are many motels and a major hotel at the edge of campus. Motels allow more persons per room, at lower per-person costs than for the on-campus dorms (as low as $25/person). Full details will be supplied in the formal *Announcement and Registration Information* that will be posted in Spring 2015.

SSAR will hold its 2015 meeting on the beautiful campus of the University of Kansas, one of America's major research universities and a world center for research and graduate education in herpetology. This will be held from **Thursday, July 30 through Monday, August 3.** All scientific sessions will be held in the Kansas Union, which is adjacent to the Museum of Natural History. The intimate campus setting will facilitate personal and friendly interactions while moderating fees for registration and lodging (see projected rates below).

This special event will include oral and poster presentations, silent and live auctions, vendor displays, student social, symposia, and special lectures provided by David Hillis (Keynote) and Miguel Vences (President's Travelogue). SSAR will resurrect popular activities from the past, including:

- Redesigned audiovisual shows arranged by David Dennis and Eric Juterbock.
- Reception honoring distinguished senior herpetologists designed so that students can interact personally with luminaries in the field.
- Herpetological Quiz, arranged by the graduate students at UT Arlington and KU, with prizes for winners.
- Live Kansas amphibians and reptiles (organized by KHS), with photographic set-ups for use by delegates.
- Tours of Fitch Reserve, site of Henry Fitch's classic long-term snake ecology work.
- Tours of the herpetological research laboratories and Biodiversity Institute.

The plenary session, keynote addresses, regular oral and poster presentations, PARC workshops, the ISHBH special session, symposia, and Seibert student award competition will all be held in the Kansas Union (*above*), a modern facility equipped with multiple restaurants, coffee shops, bowling alley, lounge, ballroom, and break-out conference rooms.

PHOTO BY TOM KENNEDY

Symposium

Frontiers in Integrative Organismal Biology: Herpetological Horizons

Organized by Rich Glor and Rafe Brown

This event will bring together a group of exceptionally research-active herpetologists working at the forefront of evolution-related fields, using amphibians and reptiles as study systems. Topics include speciation, adaptive radiation, convergence, phenotypic evolution, and the evolution of development—all through the lens of genomic approaches to understanding evolution of amphibians and reptiles. Participants include Frank Burbrink, Todd Castoe, Ben Evans, Matt Fujita, Luke Harmon, Ryan Kerney, Adam Leaché, Emily Lemmon, Jim McGuire, Rachael Mueller, Robert Thompson, and John Wiens. Summary by David Wake.

Comfortable, air-conditioned, and affordable dorm rooms located 5–15 minutes walk from the meeting venue, will be a welcomed feature of these attendee-friendly meetings. Single, dual, and four-person occupancy suites are available. Amenities include kitchen, laundry, parking, private bath, social room, etc. Naismith Residence Hall allows alcoholic beverages in rooms.

PHOTO BY DAVID M. DENNIS

NOW PUBLISHED

Contributions to the History of Herpetology

Volume 1, Revised and Expanded • Edited by Kraig Adler

In 1989, SSAR issued the first volume in what became a series of three containing the biographies (with portraits and signatures) of 786 herpetologists from throughout the world. The biographies provide key details of each person's life and education and their major contributions to herpetology and science generally, all written in an engaging style. As Jay Savage recently wrote in reviewing this series: *There is, of course, a serious problem with this great work. Once one opens it . . . one can't put it down because the next page and the page after that are so inviting!* Volume 1 has now been out-of-print for 15 years; rather than simply reprint it, **we take this opportunity to correct errors and to add 110 pages of plates and other new material**.

Volume 1 covers 152 herpetologists and includes most of the world leaders in our discipline. Their names are immediately familiar to us as authors of major works or as teachers or explorers. Many species have been named in their honor. Among them are:

• Classical authors such as Boulenger, Cope, the Duméril, Mertens, Noble, Schlegel, Schmidt, and Stejneger.

• Great naturalists who published on amphibians and reptiles: Agassiz, Cuvier, Gessner, and Linnaeus.

• Explorers such as Espada, Prince Maximilian, and Spix.

• Collection builders: Baird, Barbour, Gray, Günther, Wilhelm Peters, Seba, Steindachner, and Van Denburgh.

• Ditmars, Kauffeld, and serious amateurs like Klauber and Malcolm Smith, all of whom were popularizers.

• Authors of texts (Goin, Terentjev); great teachers (Myers, Ruthven, Wright); anatomists (Bojanus, Camp, Romer); ecologists and behaviorists (Blair, Cowles, Tinkle); etc.

• Outstanding herpetological artists such as Roesel von Rosenhof and Sordelli.

• Geographic coverage is global: North America (Cochran, Garman, Girard, Holbrook, James Peters, Pope, Taylor); Australia (Kinghorn, Krefft, Waite); Africa (Anderson, FitzSimons, Loveridge, Pitman); Russia (Bedriaga, Chernov); etc.

• Experts on taxonomic groups: frogs (Liu, Okada); salamanders (Bishop, Dunn, Sato); turtles (Carr, Siebenrock); snakes (Amaral, Blanchard, Gloyd, Jan, Maki, Russell, Wall); etc.

• Plus 81 other persons, for a total of 152 biographies.

Two sections—"Taxonomic Authors" by John Applegarth and "Doctoral Lineages" by Ronald Altig—were revised in volume 3 (2012), thus the versions in volume 1 are out-of-date and have been replaced in this new edition of volume 1 with **110 pages of new materials that supplement the biographies in volume 1**. These include original handwritten letters such as one by Linnaeus expressing his surprise at observing a siren for the first time, and another from a 20-year-old G. K. Noble, who had been a bird watcher, exclaiming his conversion: "I am a real honest-to-goodness herpetologist." **There are 60 plates (52 in full color) from classical herpetological books, many of them titles that are locked away in rare book rooms and hardly ever seen by most herpetologists. The plates have extensive captions that contain much new and important information, including details about the many outstanding artists who drew them.** All portraits from the 1989 edition have been scanned with modern laser technology for much improved quality of reproduction. A section of corrections and additions to volumes 2 and 3 is added, together with seven portraits that had been missing from the series. **A new comprehensive index, with more than 5,000 entries**, covers the entire series including all the many new persons added in the revisions to volume 1.

Specifications for Volume 1 (revised): 272 pages (8.5 × 11 inches [21.5 × 28 cm]), bound in library-grade cloth. Color frontispiece, 52 color plates; 155 portraits with signatures. Comprehensive index to series. ISBN 978–0–916984–19–9. • **Published:** August 2014. • **Prices:** Volume 1 (revised) $60. Regular prices for volumes 2 (2007; 285 biographies, 400 pp.) $65; volume 3 (2012; 349 biographies, 570 pp.) $75. **Special price for a complete set, volumes 1 (revised), 2, and 3 to SSAR members $150**; to all others $200. • **Shipping:** Add $5 per volume; non-USA, shipping at cost. • **Orders to:** SSAR Publications Secretary, P.O. Box 58517, Salt Lake City, Utah 84158–0517, USA (*telephone and fax*: 801–562–2660; *e-mail*: ssar@herplit.com). • **Payment:** Make checks payable to "SSAR." Non-USA orders must be paid in USA funds using a check drawn on an American bank or by International Money Order. Books may be charged to American Express, Discover, MasterCard, or VISA (please give account number and expiration date). • **SSAR Membership and Other Publications:** Membership information and a list of society publications can be obtained from the Publications Secretary at the address given above or at the Society's website at www.ssarherps.org.

Cover Images for *Herpetological Review*

We are looking for photographic images to appear on future covers of *HR*. To be considered, preferred images should have the following qualities:

- Should be technically superior photographs (e.g., composition, lighting, etc., should be excellent; subject must be in focus).
- Should be taken in vertical format, or, if in landscape format, permit cropping to achieve a vertical orientation (2550 × 3300 ppi).
- Should be based on film or digital media; if the latter, the native resolution must be sufficiently high to permit cropping and/or enlargement to print publication quality.
- Preference will be given to images that depict poorly known species. These could include recently described taxa or species for which a color illustration has never been published.
- Preference will be given to images that communicate some aspect of the biology of the organism (e.g., predation, feeding, courtship, crypsis).
- Images should not have been published previously nor concurrently submitted for publication elsewhere (print or electronic media).

Images for consideration should be submitted as low-resolution jpg or pdf files. Do not send full resolution images unless requested to do so. All submissions or questions should be directed to the Editor (herpreview@gmail.com).

Art in Herpetology

As space and available material permit, we will occasionally publish examples of historical as well as contemporary herpetological art. We welcome the submission of historical material under the following conditions:

- The work should be copyright-free and be provided as a high-resolution digitized file (consult Herpetological Art and Illustration Coordinator or Editor for specifications).
- Accompanying text should provide information on the subject matter, artist/illustrator, and publication source. Include references as needed to appropriately attribute information from other sources.

Contemporary artists are invited to submit their own work for publication:

- Artist will retain copyright of all submitted material.
- Accompanying text should provide information about technique, media, or other information likely to be of interest, especially to other artists. Other details of interest include the source of illustration subject (e.g., scientific name, geographic origin, etc.) or the work (e.g., book publication, etc.) for which the illustration was produced.
- Artists are welcome to include contact information (e.g., email address, website location), as well as indicating whether original art or prints are available for sale or if the artist is available for commissioned work.

Material may be submitted for review to Jackson Shedd, Herpetological Art and Illustration Coordinator at jackson_shedd@sbcglobal.net.

INFORMATION FOR CONTRIBUTORS

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes concerning the study of amphibians and reptiles, as well as book reviews, commentaries, regional and international herpetological society news, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (for information, please refer to: http://www.ssarherps.org/pages/JHinstr.php). To submit a manuscript to ***HR***, please consult the SSAR webpage at:

<http://www.ssarherps.org/pages/HRinfo.php>

REPRINTS AND PAGE PROOFS

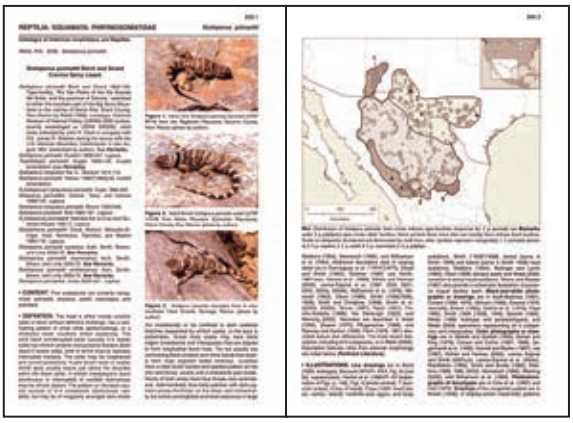
Page proofs are sent electronically to authors of all articles, book reviews, and obituaries, but are not prepared for natural history, geographic distribution, or herpetoculture notes. Proofs are sent as pdf files approximately 2–4 weeks prior to publication. High resolution electronic (pdf) reprints of notes, articles, book reviews, and obituaries are provided at no charge to the primary/corresponding author as a benefit of SSAR membership. Reprint files will normally be sent prior to the issue mailing date from the printer. Authors who are not current SSAR members may purchase pdf reprints from the SSAR Publications Office.

ADVERTISING

Herpetological Review accepts commercial advertising. Rates and copy information are available from the SSAR web page (http://www.ssarherps.org/pages/HRinfo.php).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at the Department of Natural Sciences, Williams Baptist College, P.O. Box 3692, Walnut Ridge, AR 72476, USA. Periodicals postage paid at Walnut Ridge, AR 72476 and at additional mailing offices.

All rights reserved. No part of this periodical may be reproduced without written permission of the Editor, except that authors and their agents are permitted to reproduce and distribute their own articles and notes.



POSTMASTER: Send address changes to Breck Bartholomew, SSAR Publications Secretary, P.O. Box 58517, Salt Lake City, UT 84158. **MISSING OR DAMAGED ISSUE?** Please notify Breck Bartholomew, SSAR Publications Secretary (e-mail: ssar@herplit.com) for a replacement.

SSAR PUBLICATIONS

SSAR publishes seven different series: *Journal of Herpetology, Herpetological Review, Facsimile Reprints in Herpetology, Contributions to Herpetology, Herpetological Circulars, Herpetological Conservation*, and the *Catalogue of American Amphibians and Reptiles* (see below for CAAR details). SSAR members receive pre-publication discounts on all *Facsimiles* and *Circulars* and on volumes in the *Contributions* and *Herpetological Conservation* series. A complete pricelist of Society publications is available at: http://www.ssarbooks.com/.

CATALOGUE OF AMERICAN AMPHIBIANS AND REPTILES

The *Catalogue* consists of individual accounts of species and genera prepared by specialists, including synonymy, definition, distribution map, and comprehensive list of literature for each taxon. The accounts cover amphibians and reptiles of the entire Western Hemisphere. As of 2014, SSAR is making all CAAR accounts OPEN ACCESS as a service to the herpetological community. To access individual accounts, visit http://www.ssarcaar.com.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

www.ssarherps.org

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology*, and its bulletin, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*.

To join SSAR or to renew your membership, please visit the secure online ZenScientist website via this link:
http://www.ssarherps.org/pages/membership.php

Future Annual Meetings
2014 — Chattanooga, Tennessee, 30 July–3 August (JMIH with ASIH, HL, and AES)
2015 — Lawrence, Kansas 30 July–3 August (SSAR with PARC and KHS)

New Ecological Data on the Family Salamandridae in the Maghreb

North Africa is a biodiversity hotspot, where species of Eurasian, tropical African, and Saharo-Arabian origins co-occur (Oosterbroek and Arntzen 1992; De Jong 1998; Sanmartin 2003). The family Salamandridae originated in Europe (Zhang et al. 2008) and is represented in north Africa by two genera, *Salamandra* and *Pleurodeles* (Schleich et al. 1996). The genus *Pleurodeles* contains three species: *P. waltl* Michahelles, 1830, *P. nebulosus* (Guichenot, 1850) and *P. poireti* (Gervais, 1835). *Pleurodeles waltl* occurs in the Iberian Peninsula and in northwestern Morocco, on the Atlantic plain, in the area delineated by Tangiers, Safi, and Essaouira (Bons and Geniez 1996; El Hamoumi and Himmi 2010), and also extending inland to the Middle Atlas and Rif Mountains (Pasteur and Bons 1959; Mellado and Mateo 1992; Fahd and Mediani 2007), where its range extends locally to an altitude of 1300 m (Bons and Geniez 1996). *Pleurodeles nebulosus* is endemic to northern Tunisia, occurring in the region between Kroumiria, Cap Bon (Ben Hassine et al. 2013), and northern Algeria, and extending westwards as far as Oran according to historical records (Guichenot 1850; Doumergue 1901). In this region, it mainly occupies lowland areas, extending to altitudes of 930 m in northwestern Tunisia (Ben Hassine et al. 2013) and 600 m in Algeria (Samraoui et al. 2012). The third species, *P. poireti*, is a microendemic species, restricted to the Edough Peninsula in northeastern Algeria (Carranza and Wade 2004; Brunet et al. 2009).

Salamandra algira Bedriaga, 1883 occurs in northern Morocco and Algeria, mainly in mountain ranges, usually between 500 and 2010 m in elevation (Doumergue 1901; Geniez and Soto 1994; Escoriza and Comas 2007; Samraoui et al. 2012), although under favorable conditions this species can also occur at lower altitudes (Martínez-Medina et al. 1997; Martínez-Medina 2001). In Morocco, three alloparapatric subspecies have been described: *S. algira tingitana* Donaire-Barroso and Bogaerts, 2003, located in the extreme northwest; *S. algira splendens* Beukema, de Pous, Donaire-Barroso, Bogaerts, Garcia-Porta, Escoriza, Arribas, El Mouden and Carranza, 2013, present in the Middle Atlas and Rif Mountains; and *S. algira spelaea* Escoriza and Comas 2007, occurring on the Beni Snassen Massif (Escoriza and Comas 2007; Beukema et al. 2013). The populations of *S. algira* in Algeria differ genetically from the Moroccan subspecies and the nominotypical

subspecies may be endemic to Algeria (Steinfartz et al. 2000; Escoriza et al. 2006). These subspecies occur in isolation from each other in sub-humid and humid montane forests (Mateo et al. 2003; Escoriza and Comas 2007).

Here we provided new data on North African salamandrids, examining their regional and local niche based on occurrence data and GIS supported climatic layers. We also describe breeding habitats and determine co-occurring amphibian assemblages and larval ecomorphological guild. These data provide new insights on the autecology of these poorly known species (Stuart et al. 2008), which may help inform their management, particularly as *P. waltl* is classified as a Near Threatened, and *P. nebulosus* and *S. algira* as Vulnerable (IUCN 2013).

MATERIALS AND METHODS

Climate and land-cover data.—We compiled 136 geo-referenced records of the three species across Morocco and Tunisia (Fig. 1A). Presence records were included in this analysis when were separated by more than 1 km, resulting in 92 records in Morocco (41 *P. waltl,* 30 *S. algira tingitana,* 17 *S. algira splendens,* and 4 *S. algira spelaea*); and 34 in Tunisia (all *P. nebulosus*). Locality coordinates were collected using a Garmin Dakota 100 GPS.

Topographic and climatic data were extracted at a resolution of 30 arc seconds from WorldClim layers (Hijmans et al. 2005) using the DIVA GIS 7.5 package (Hijmans et al. 2012). The climatic variables examined were mean annual temperature, maximum temperature in the warmest month, minimum temperature in the coldest month, and mean annual precipitation. These variables describe the thermal ranges and water availability that determine the distributions of amphibians in temperate climates (Buckley and Jetz 2007). These data were interpreted according to the FAO climatic classification (http://www.fao.org/geonetwork), which is based on Penman's method (Tanner and Pelton 1960), for establishing the aridity threshold under Mediterranean conditions; i.e., at a mean annual precipitation around 450–500 mm, defined as semi-arid (conditions above this threshold are defined as humid or sub-humid). The segregation of the three species in the regional niche was analyzed by Constrained Correspondence Analysis (CCA), based on three variables, mean annual temperature (°C), altitude (m) and annual precipitation (mm). The CCA is useful to determine variations in species occurrence in relation to a matrix describing an environmental gradient, and has been

TABLE 2. Type of land cover at terrestrial habitats surrounding North African urodele breeding sites. Land cover types obtained from GlobCover 2009 database.

Species	Land cover type	(%)
P. waltl	Mosaic cropland (50–70%) / vegetation (20–50%)	40
	Rainfed croplands	22
	Mosaic vegetation (50–70%) / cropland (20–50%)	17
	Mosaic grassland (50–70%) / forest or shrubland (20–50%)	12

widely used to describe the structure of amphibian assemblages (Pillsbury and Miller 2008; Furlani et al. 2009). The significance of the model was examined using permutation tests (Oksanen et al. 2012). This analysis was performed using the vegan package (Oksanen et al. 2012) for R (R Core Development Team 2011). We also examined the effects of vegetation cover on the occurrence of these species, because vegetation cover is a major influence on the composition of salamander assemblages (Pough et al. 1987). The land-type data were obtained from the database GlobCover (2009), which classifies land cover into 23 categories, from forests to urban areas, based on satellite photographs with a spatial resolution of 300 m (Bontemps et al. 2011). This database provides a classification based on global vegetation types, so these categories are described according to local vegetation communities (Benabid 1985; El Hamrouni 2001; Aafi et al. 2002; Benabib 2002; Brun 2007; Stambouli-Essassi et al. 2007; Valdés et al. 2006).

Breeding habitat characterization.—We encountered urodela species in a total of 136 aquatic breeding habitats (Fig. 1 B) including temporary ponds, permanent ponds, springs, and stream pools. These aquatic habitats were surveyed between December and April in Morocco and between March and April in Tunisia. These times were chosen as *S. algira* breeds in autumn-winter (October to March), but there is increased activity of other amphibian species in spring (March to May) in the Maghreb, with the exception of *Pelophylax saharicus* (Doumergue 1901; Ben Hassine et al. 2013; Mayet 1903; Escoriza and Comas 2007; Ben Hassine et al. 2013). At each breeding habitat, we measured average water body depth (cm), surface area (m²), slope, temperature (°C), dissolved oxygen (mg/L), pH and conductivity ($\mu S \cdot cm^{-1}$). Average depth was taken as the mean value of five successive measurements from the shore to the centre. Surface area was obtained by measuring the maximum length of the longitudinal axis and the length of the transverse axis, and assuming an elliptical shape. In ponds larger than 100 m², surface area was estimated using a Garmin Dakota 100. The pond slope was calculated following the equation:

$$\text{Slope} = \text{maximum depth} / \{\text{sqrt (surface area} / 2)\}$$

Turbidity was assessed using a scale ranging from 1 (transparent waters\10 Nephelometric Turbidity Units; NTU) to 3 (very turbid waters\300 NTU) based on light extinction estimated at Secchi disk depth. The percent of emergent vegetation covering the pond surface was estimated from photographs. Chemical water parameters were measured in situ using a Crison 524 conductivity meter (for conductivity), an EcoScan ph6 (for pH) and a Hach HQ10 Portable LDO meter (for dissolved oxygen). Aquatic habitats were sampled on sunny days between 1200 h and 1500 h in order to maintain maximum homogeneity in the measurements.

Species co-occurrence.—Salamander species are keystone predators, regulating the composition of anuran assemblages in aquatic habitats (Morin 1983; Wilbur 1987; Portheault et al. 2007). For this reason we examined the composition of anurans in the breeding habitats where salamander larvae were observed. These occurrence data were included in a presence–absence matrix, which was used to calculate an overlap metric, Pianka's index (Pianka 1973). This index assumes values between 0 (null overlap) and 1 (complete overlap). This index was computed using the package spaa (Zhang 2013) in R (R development Core Team 2011).

Morphological data.—To classify salamander species into morphofunctional groups, we measured several morphological characters of the larvae. Classification of larvae based on such external traits can serve as a proxy for larval niche, because these characters are related to the selection of specific niches, namely lotic or lentic habitats (Petranka 1998). We included in this analysis specimens of *Pleurodeles* with five well-formed digits on the hind limb and fully developed external gills (stages 54–55; Gallien and Durocher 1967), and all larvae of *S. algira* because part of their larval development is intrauterine (Veith et al. 1998). The morphological data were obtained by the digital analysis of photographs, following the procedure detailed in Escoriza and Boix (2012), using the program SigmaScan Pro vs 5.0.0 (1987–1999 SPSS Inc.).

Variables measured were body length (from the snout tip to the end of the tail), body depth (dorsal–ventral distance measured in the mid-point between the front and hind limbs), and fin length (from the tip of the tail to the end of the dorsal insertion). We calculated the span ratio based on these measurements; i.e., the ratio between the longitudinal (total length) and transverse axes (body depth). These measures are useful for classifying Urodela larvae into two ecomorphs: the stream type (streamlined shape and short caudal fin) and the pond type (more oval shape and extended caudal fin; Valentine and Dennis 1964; Petranka 1998).

RESULTS

Regional niches: climate and land-cover type.—Species appear to be segregated along a climatic and topographic gradient (Fig. 2). The overall test indicated that the model performed better than the random models ($F = 28.73$, $p = 0.005$). The two first CCA axes were significant (CCA 1: $F = 72$, $p = 0.005$; CCA 2: $F = 14$, $p = 0.005$, after 199 permutations). In the first axis (eigenvalue = 0.67) altitude was the variable with the higher score (0.93) compared to annual temperature (-0.86) and annual precipitation (0.51). In the second axis (eigenvalue = 0.13), precipitation was the variable with the higher score (-0.56) followed by temperature (0.26) and altitude (-0.08). This result suggests that altitude and temperature are important factors explaining the occurrence of

Salamandridae species in the region. *P. waltl* and *P. nebulosus* appear in humid to semi-arid zones (Table 1). Both *Pleurodeles* species occur mainly along coastal plains with temperate winters and warm summers. *Salamandra algira* inhabits sub-humid to humid climate areas (although *S. algira spelaea* at the Beni Snassen Massif occurs within the semi-arid zone) with a temperate-to-cold winter climate variant (Table 1).

Land cover categorization and field observations show that *P. waltl* occurs mainly in open landscapes, usually agricultural areas, with some patches of natural vegetation dominated by evergreen oak (*Quercus suber*) forests and isolated trees of wild olive *Olea europea* and carob *Ceratonia siliqua*, associated with a dense to open underbrush formed by dwarf palms *Chamaerops humilis* and *Pistacia* species (Table 2). *Pleurodeles nebulosus* also occurs in mainly agricultural landscapes with some scattered formations of dense shrubs, usually formed by *Q. coccifera*, *Halimium halimifolium*, and *Pistacia* species. In north-western Tunisia, *P. nebulosus* inhabits humid montane forests (800–1100 m in elevation) composed of the deciduous oak *Q. canariensis* associated with *Alnus glutinosa*, and at lower altitudes (below 800 m), mixed formations of *Q. canariensis*, *Q. suber*, *Q. ilex*, and *Q. coccifera* associated with a dense subtropical-like understory of small trees and bushes, such as *Arbutus unedo*, *Laurus nobilis*, and *Erica arborea*.

Salamandra algira inhabits more closed landscapes, usually thermic or mesothermic Mediterranean forests (at altitudes of 0–1400 m) composed of *Q. suber*, *Q. faginea*, *Q. canariensis*, *Pinus halepensis*, *Juniperus phoenicea*, and *Tetraclinis articulata*, as well as supra-Mediterranean forests (1400–1800 m) composed of the Atlas Cedar (*Cedrus atlantica*) and Moroccan Fir (*Abies maroccana*). Locally, it also occurs in more open habitats, such as alpine meadows (in the Bou Iblane region and the Middle Atlas) and in barely vegetated karst formations (Tingitana Peninsula).

Aquatic habitat selection, ecomorphs, and species co-occurrence.—The studied species were found in 136 breeding habitats, described as follows: *P. nebulosus* (N = 42), *P. waltl* (N = 68), *S. algira tingitana* (N = 11), *S. algira splendens* (N = 11), and *S. algira spelaea* (N = 4) in Morocco (Fig. 1B). Species of the genus *Pleurodeles* usually breed in temporary ponds, tolerating large variations in water chemistry, turbidity, and density of aquatic vegetation, although the turbidity is usually high, with a dense layer of vegetation formed by buttercup species of the genus *Ranunculus* (Fig. 3; Table 3). According to our observations, both *Pleurodeles* species breed in water bodies with moderate to large dimensions, appearing to avoid those of small size and running waters. *Salamandra algira* larvae were found in different types of water bodies, ranging from temporary ponds to stream pools, but they were most commonly found in springs. These springs frequently had clear water and low-density aquatic vegetation (Fig. 3; Table 3). In these aquatic habitats, we sampled a total of 334 larvae of urodeles (*P. waltl*: N = 231; *P. nebulosus*: N = 34; *S. algira*: N = 69) (Table 4). Prometamorphic *P. waltl* attained larger body sizes compared to the same stage of *P. nebulosus*, and both species had a compressed shape (i.e., small span ratio), with a dorsal fin extending along the dorsum (Fig. 4A; Table 4). Both species had no members at hatching, and balancers that are lost within a few days of hatching as the limbs and digits develop (Figs. 4A, 5). This corresponds to the pond-type morphology. In contrast, *S. algira* shows a more streamlined morphology (i.e., higher span ratio), with the dorsal fin ending at the base of the tail and members present at hatching (Fig. 4 B), which corresponds to the stream-type morphology. These findings are consistent with those obtained for the characterization of aquatic habitats; i.e., the species of the genus *Pleurodeles* appeared predominantly in temporary ponds, whereas *S. algira* occurred in springs.

The breeding sites used by the two genera differ in the species composition of co-occurring anurans. In the studied areas, *P. waltl* and *P. nebulosus* co-occurred with 100% of the sympatric anuran species (i.e., those found in the same geographic region, but not necessarily in the same habitats) whereas *S. algira* only with 33% of the sympatric species (Table 5).

Discussion

Salamandra and *Pleurodeles* appear to segregate along a thermal and rainfall gradient, both of which are correlated with altitude (Peel et al. 2007), and occupy terrestrial habitats with differing vegetation structures. *Salamandra algira* tends to occupy humid and colder conditions, with relatively dense

vegetation cover, whereas both *Pleurodeles* species appear well adapted to open anthropic landscapes in warmer maritime climates. Similar patterns also appear in the southwest of the Iberian Peninsula, where the genus *Salamandra* occurs in forests at mid-altitudes, whereas *P. waltl* is more common in lowland agricultural landscapes (Buckley and Alcobendas 2002; García-París et al. 2004). However, in the western Rif (Morocco) and north-western Tunisia, *Pleurodeles* populations occur at mid-altitudes, in humid oak woods (Fahd and Mediani 2007; Ben Hassine et al. 2013). In this mountains region of Morocco, *P. waltl* may appear in sympatry with *S. algira*. This highlights the ecological plasticity of the genus *Pleurodeles*, which is capable of inhabiting both lowland agricultural landscapes and dense montane forests.

Our findings also indicated that *P. waltl* and *P. nebulosus* had a moderate to high degree of habitat overlap with several species of anurans. *Pleurodeles* species breeding sites were frequently associated with anurans that breed in ponds with moderate-long hydroperiods (more than 2–3 months), as is the case of *P. waltl* and *Pelobates varaldii* in Moroccan coastal plains (Escoriza and Ben Hassine 2013), or *P. nebulosus* and *Hyla meridionalis* in northern Tunisia (Ben Hassine and Nouira 2012) but also with more generalist species, like *Discoglossus pictus*, *Discoglossus scovazii*, *Amietophrynus mauritanicus* and *Bufotes boulengeri*. In natural conditions, *Pleurodeles waltl* and *P. nebulosus* could be potential predators on the eggs and larvae of anurans (Diaz-Panigua et al. 2005; Ben Hassine et al. 2013) and under laboratory conditions, *P. waltl* exert intense predation in anuran larvae, at least on small benthic species (Portheault et al. 2007). However, in the field, the size of the anuran larvae (e.g., *P. varaldii*; Escoriza 2013), strategies of predator avoidance (e.g., in the case of *Hyla* species; Chovanec 1992), and large clutch sizes (e.g., up to 1000 for the genus *Discoglossus* and *Hyla*, and up to 20,000 eggs for Bufonidae species in North Africa; Pasteur and Bons 1959; Schleich et al. 1996) can explain the tadpole survival of these co-ocurring anurans. Differences in the breeding timing of other anurans, such as *Pelophylax saharicus* (which start to breed later in the season, usually in mid-spring and breed mainly in permanent ponds; Pasteur and Bons 1959) may explain the absence of breeding habitat overlap with the *Pleurodeles* species. The breeding habitat of *S. algira* overlaps those of fewer anuran species, possibly because *S. algira* usually breeds in smaller water bodies (which support lower species richness; Werner et al. 2007) and can start to reproduce in late autumn, when many anurans have not yet commenced their reproductive season (Pasteur and Bons 1959). Our morphological analysis demonstrates important differences between the larvae of these two Salamandridae genera, and that their larvae correspond to two clear different ecomorphs, suggesting the segregation of their larval niches. All these factors combined (i.e., differences in thermal ranges, land-cover types, and larval habitat selection) act to reduce the habitat overlap between the species of the two genera, in those areas where they co-occur geographically (e.g., in northwestern Morocco; Bons and Geniez 1996).

In recent decades, there have been significant changes in the habitats of the northern Maghreb, which have caused the rarefaction of numerous species of vertebrates (Mehlman 1984; Le Cuziat et al. 2005). Similarly, several wetlands have been destroyed on the Atlantic plains of Morocco (Emberger 1939; Green et al. 2002) and in Tunisia (Mehlman 1984; Ben Hassine and Nouira 2012), and this destruction has been linked to the extinction of many populations of *Pleurodeles* (Werner 1931;

TABLE 5. Habitat overlap values (Pianka's index) among studied urodeles and co-occurring anuran species in the Maghreb. *S. algira** = *S. algira splendens* and *S. algira tingitana*; *S. algira*** = *S. algira spelaea*; A.ma. = *Alytes maurus*, ; D.p. = *Discoglossus pictus*; D.s. = *Discoglossus scovazzi*; P.v. = *Pelobates varaldii;* B.bl. = *Bufotes boulengeri*; A.m. = *Amietophrynus mauritanicus*; H.m. = *Hyla meridionalis*; P.s. = *Pelophylax saharicus.* No = species did not occur in sympatry with the studied species; N = number of localities.

Joger 2003; Ben Hassine and Nouira 2012). The degradation of forests (Zaimeche and Sutton 1997) is also related to the local extinction of some populations of *S. algira* (Escoriza et al. 2013). This process of deforestation possibly affect more severely to *S. algira* that to the species of genus *Pleurodeles*, which can succesfully occupy more open landscapes, such as agricultural fields. Other threats include the introduction of exotic species like Pumpkinseed Sunfish (*Lepomis gibbosus*), the Mosquitofish (*Gambusia holbrooki*), and crayfish (*Procambarus clarkii*), which we found even in protected areas, including the Merja Zerga RAMSAR reserve, although they occur over much of the North African wetlands (Samraoui et al. 2012; Ben Hassine et al. 2013). These exotic species usually occur in large ponds (Cruz and Rebelo 2007), as those used by *P. waltl* to reproduce, and can cause a rapid depletion of its populations as is reported in southwestern Europe (Cruz et al. 2008).

Acknowledgments.—We are very grateful to anonymous reviewers for their substantial contribution to the improvement of this paper. Permits for fieldwork were provided by the Ministère d'Agriculture in Tunisia and Le Haut Commissariat aux Eaux et Forêts et à la Lutte Contre la Désertification in Morocco. Authors were supported by a grant from The Mohamed bin Zayed Species Conservation Fund (13057819).

American Alligator Nests as Microhabitat for a Diversity of Vertebrates

The American Alligator (*Alligator mississippiensis*) is a New World crocodilian that builds mound nests using available vegetation and substrate (Joanen and McNease 1989). The geographic range of alligators covers a diverse array of habitats which includes marshes, swamps, upland lakes, bayous, and river backwaters (Giles and Childs 1949; Goodwin and Marion 1979). Alligators significantly alter available habitat by digging holes (Beard 1938; Craighead 1968; Kushlan 1972) and contructing nest mounds (Joanen and McNease 1989). Kushlan (1974) described the use of alligator holes as refugia for aquatic organisms in times of drought, and credits alligator habitat reconstruction for maintaining richness and diversity of southern Florida's unique habitats. Nest construction by a single female also results in considerable habitat alteration. Nests are typically characterized by an area of devegetation, 3–7 m in diameter, uprooted vegetation or substrate, a mound, and usually an associated den(s) in the water nearby the nest (Joanen 1969).

Numerous observations have noted the use of alligator nest mounds as proxy nesting habitat by other reptiles (Dietz 1979; Kushlan and Kushlan 1980). Thus, alligators play a complex role in the ecosystems they inhabit beyond that of an apex predator (Kushlan and Kushlan 1980). This study aims to describe the diversity of vertebrates associated with alligator nests and discuss the nature of their associations using data collected during multiple, studies unrelated to the use of nests by other species.

Methods.—Sixty-six alligator nests were observed at three different sites during the course of this study; 34 at J.D. Murphree Wildlife Management Area in southeastern Texas, 22 in Las Conchas Marsh in southeastern Louisiana, and 6 in Eufaula National Wildlife Refuge in eastern Alabama (all USA). Data for this study were collected during field work for other projects via personal observation and game camera traps employed at nesting sites. Game cameras were set to record one still photograph every 5 minutes using a battery-operated light board that signaled an IR sensor on a camera (Merchant et al. 2013). Nests were visited weekly from the onset of construction until egg hatching from

TABLE 1. Vertebrates associated with American Alligator nests, and their observed activities.

Class	Species	Association type
Aves	Coot (*Fulica caribaea*)	Feeding
	Purple Gallinule (*Porphyrio martinica*)	Feeding
	Boat-tailed Grackle (*Quiscalus major*)	Feeding
	Great-tailed Grackle (*Quiscalus mexicanus*)	Feeding
	Louisiana Night Heron (*Nycticorax nycticorax*)	Feeding
	Limpkin (*Aramus guarauna*)	Feeding
	Great Blue Heron (*Ardea herodias*)	Feeding
	American Egret (*Ardea alba*)	Feeding
	Snowy Egret (*Egretta thula*)	Feeding
	Cattle Egret (*Bulbulcus ibis*)	Feeding
	Reddish Egret (*Egretta rufescens*)	Feeding
	Least Bittern (*Ixobrychus exilis*)	Feeding
	Little Blue Heron (*Egretta caerulea*)	Feeding
	Black-crowned Night Heron (*Nycticorax nycticorax*)	Feeding
	Glossy Ibis (*Plegadis falcinellus*)	Feeding
	American Bittern (*Botaurus lentiginosus*)	Feeding
	Tricolor Heron (*Egretta tricolor*)	Feeding
	Green Heron (*Butorides virescens*)	Feeding
	Mourning Dove (*Zenaida macroura*)	Feeding
	Belted Kingfisher (*Megaceryle alcyon*)	Feeding
	Mockingbird (*Mimus polyglottos*)	Feeding
Mammalia	Raccoon (*Procyon lotor*)	Feeding
	Feral Hog (*Sus scofra*)	Feeding
	Hispid Cotton Rat (*Sigmodon hispidus*)	Nesting
	Norwegian Rat (*Rattus norvegicus*)	Nesting
	Marsh Rice Rat (*Oryzomys palustris*)	Nesting
	Mice?	Nesting
	Eastern Cottontail Rabbit (*Sylvilagus floridanus*)	Unknown
	Swamp Rabbit (*Sylvilagus palustris*)	Unknown
	Gray Fox (*Urocyon cinereoargenteus*)	Feeding on rodents?
	Bobcat (*Lynx rufus*)	Feeding on rodents?
Reptilia	American Alligator (*Alligator mississippiensis*)	Nesting/Basking
	Red-eared Slider (*Trachemys scripta*)	Nesting/Basking
	Stinkpot (*Sternotherus odoratus*)	Nesting
	Yellow-bellied Water Snake (*Nerodia erythrogaster*)	Nesting/Basking

2010 through 2012 at J. D. Murphree WMA. Data was collected during the same season in 2010 and 2011 at Las Conchas Marsh, and only during the 2012 nesting season at Eufaula NWR. Animal species that were identified from photographs were taxonomically organized for alpha diversity. Abundance was not taken into account.

Results and discussion.—Of 34 vertebrate species observed associated with alligator nest mounds, 22 were birds (Table 1, Fig. 1), 14 of which were wading birds or waterfowl. At least ten mammal species were observed associated with nest mounds (Fig. 2). Three species of murids were identified: the Marsh Rice Rat (*Oryzomys palustris*), the Hispid Cotton Rat (*Sigmodon hispidus*), and the invasive Norway Rat (*Rattus norvegicus*). Other murid species could not be identified because of their small size and the low resolution of the game camera, thus we have characterized the number of mammal species as "at least ten." Aside from nesting female alligators, reptile species identified included two turtle species (*Trachemys scripta* and *Sternotherus odoratus*), representing two different families, one water snake (*Nerodia erythrogaster*), and one juvenile American Alligator (Table 1). Ants and termites (species unknown) were also observed colonizing nests when we excavated the nests, but were not identified to lower taxonomic levels.

The nature of the association between observed species and alligator nests varied among taxonomic groups. Birds were observed primarily using nests mounds as staging grounds to feed in nearby water or directly feed on invertebrates associated with the nests, although the photos selected do not necessarily reflect these activities, as they were chosen on the basis of clarity and position so as to make identification easier for the reader. Of mammal species, raccoons and feral hogs were observed during the predation of alligator eggs. At least three species of murids (and two other unidentified species) were observed nesting within alligator nests (Table 1). Associations of the Bobcat and rabbits with nests were undetermined. We speculate that Bobcat and Gray Fox were hunting rodents that lived within the nests, and that both rabbit species were using the elevated nests for defecation. Both turtle species were observed nesting in old alligator nests, while only one (*Trachemys scripta*) was seen basking on alligator nests. *Nerodia erythrogaster* was also observed in close association with a nest, using it for basking and was later determined to have deposited offspring in the same nest, although the mother is unconfirmed. The use of old crocodilian mound nests by nesting tutles is probably a common event, as several turtles, including *Trachemys dorbigni* and *Phrynops hilari*, commonly use the nests of *Caiman latirostris* in Argentina for deposition of eggs (Alba Imhoff, pers. comm.).

Alligators play a complex role in wetland ecosystems (Kushlan and Kushlan 1980), and this study expands our understanding of that function from the prespective of nest mounds alone. Such architecture may increase available terrestial space in marsh systems and serve as functional refugia or advantageous structures for many taxa. Alligators guarding their nests may deter nesting turtles from using the mounds (Kushlan and Kushlan 1980). However, differences in maternal attendance by individual alligators and differences in maternal nest defense intensity may allow some taxa to associate with alligator mounds, which would protect them from other predators, or allow the predation of alligator eggs.

Acknowledgments.—We acknowledge the help of J. Sutherlin, manager of J. D. Murphree Wildlife Management Area, in Port Arthur, Texas, for permission to conduct these studies on Texas Parks and Wildlife refuge land. In addition, we thank Justin Hoffman (McNeese State University) and David W. Morris (Auburn University) for their help in the identification of murid and bird species, respectively, in nest photographs.

Road Effects on Amphibian Populations: Vehicles as a Means of Dispersal in Treefrogs

No matter where we look it is clear to see that humans have altered Earth's ecosystems (Vitousek et al. 1997). Amphibians as a single group have been disproportionately impacted by these alterations (Stuart et al. 2004) and have therefore received an enormous amount of scientific and public attention in trying to understand the mechanisms of decline as well as potential solutions to them (for review see Beebee and Griffiths 2005). One often cited mechanism of decline is habitat loss and fragmentation (for review see Cushman 2006), in particular the effects of urbanization (Hamer and McDonnell 2008) and the roads associated with it (Findlay and Bourdages 2000; Hels and Buchwald 2001).

Roads in general represent one of the most widespread impacts on natural ecosystems and have been shown to have negative effects on a diverse set of organisms (for reviews see Spellerberg 1998; Trombulak and Frissell 2000). A recent synthesis of over 40 years of data concerning road mortality on amphibians clearly demonstrated the profound negative impact roads are having on amphibians and that current mitigation efforts are not likely to ameliorate this threat (Beebee 2013). In addition to direct mortality, roads are a major source of habitat fragmentation leading to decreased connectivity within landscapes and ultimately altering dispersal patterns of wildlife (Clobert et al. 2001). Amphibians are often cited as having low dispersal rates and capacity in an already naturally patchy environment, which exacerbates the negative impact of habitat fragmentation by roads (Cushman 2006; Hamer and McDonnell 2008). Safner et al. (2011) concluded that habitat fragmentation due to roads could lead to demographic and genetic isolation of amphibian populations, which is likely to result in a higher extinction risk.

However, despite the clear negative impacts of roads there are certain instances where roads may positively impact amphibian populations. For instance, amphibians have been shown to utilize roadway ditches, canals, and hedgerows as a means of dispersal through the landscape (Brown et al. 2006; Ficetola and DeBernardi 2005). Frogs of the genus *Eleutherodactylus* have been documented to use the transport of horticultural materials as a means of unintentional dispersal to a number of locations throughout the world (Kraus et al. 1999 and citations therein). Traffic itself has also been implicated as a dispersal mechanism for plant species with particular emphasis being given to the spread of invasive species (Spellerberg 1998 and citations therein). Duffield and Bull (2002) reported on a male Gidgee Skink (*Egernia stokesii*) that was inadvertently transported to a new location by a research vehicle in Australia. But direct traffic dispersal mechanisms have received little to no attention in the amphibian literature. Herein I report on personal observations made over a two-week period in which my vehicle was directly used as a dispersal mechanism for both native and non-native treefrogs and I discuss future directions to explore and expand on these observations.

Observations.—Over a two-week period (16–20 and 23–27 September 2013), I recorded six instances of transporting treefrogs via my vehicle while travelling from my home in

JOHN E. HERMAN

e-mail: jherman@fgcu.edu

FIG. 1. An *Osteopilus septentrionalis* juvenile on my driver-side mirror at 0648 h on 25 September 2013. This individual jumped off the mirror shortly after I left my driveway and was not transported to Florida Gulf Coast University.

Southwest Florida to my place of employment at Florida Gulf Coast University (FGCU). My vehicle is a black Nissan Titan pickup truck with an open bed and a black plastic bed liner. In every instance my vehicle had been parked in the same spot during the night and was wet in the morning either from rain, community sprinklers or condensation. The environment surrounding where I was parked is a typical south Florida residential landscape of manicured lawns, ornamental shrubs, trees, and palms, a water retention pond and high house density (average lot size approximately 700 m^2). The observation and travel times were between 0630 h and 0730 h lasting approximately 25 minutes. The route of travel was always the same, resulting in a linear movement of 12 km and a road distance of 22 km.

The first instance of vehicular dispersal involved a juvenile Green Treefrog (*Hyla cinerea*) and an adult Squirrel Treefrog (*Hyla squirella*). The juvenile *H. cinerea* was observed before I left my home and was hiding in-between the plastic housing and the backside of the driver-side mirror. For almost the entire drive to FGCU I was able to make visual contact with the frog. Upon arriving at FGCU as I opened the driver-side door the frog leaped out from behind the mirror and quickly made its way into some tall grass. As I closed the door and began to walk around the truck I observed the adult *H. squirella* in the bed of the truck near the tailgate. I chose not to harass the frog and when I returned at the end of the day the frog was no longer there. So, I assumed that the frog had been there since I left my home and that it left the truck at some point during the morning as the sun rose and made the truck bed an unpleasant thermal environment.

After this first instance I began to do a quick survey of my vehicle before I left each morning. On 9 of the 10 days during the observation period I observed treefrogs on my vehicle, usually on the windshield, in the bed, or in/on the mirrors (Fig. 1). In total I observed 31 frogs (including the 2 from the first instance; Table 1) using my truck as early morning habitat; 5 individuals were *H. cinerea* (all juvenile), 3 were *H. squirella* (2 adults and 1 juvenile), and the remaining 23 were the exotic invasive Cuban Treefrog (*Osteopilus septentrionalis*; 4 adults and 19 juveniles). Only five other times (after the first instance) did I observe the frogs at my house and then again when I arrived at FGCU. The 6 frogs (not including the first 2) that made the whole journey and then were not relocated on my truck at the end of the day were juvenile *O. septentrionalis* (2 on the driver-side mirror, 3 in the bed, and 1 actually made the whole trip on my windshield). I observed 15 of 23 frogs (not including those that made it all of the way to FGCU) leaping from my vehicle when I was still within my housing development and while the truck was moving. The other 8 frogs (1 *H. cinerea* juvenile, 1 *H. squirella* adult, 2 *O. septentrionalis* adults, and 4 *O. septentrionalis* juveniles), I did not directly observe leaving my vehicle nor did I observe them when I reached FGCU. So, they either leapt off at some point during transport, made it to FGCU without my detection, or remained on my vehicle throughout the day and I possibly transported them back to my home or some other unknown destination.

Discussion.—I suspect that all of my observations were highly dependent on weather patterns and time of year. The summer

of 2013 was an exceptionally wet and rainy season in Southwest Florida. Additionally, I had seen and heard a lot of reproductive effort from all three of these treefrog species leading up to and during the period of observation, which may account for the prevalence of juvenile treefrogs in my data. This mechanism for dispersal may not be as intense at other times of year or during drier years. However, given the fact that I did observe at least 1 adult being transported, it may still have an impact on population dynamics.

In addition to my data, during informal conversations with colleagues and students regarding these observations, I have had a high percentage of people confirm similar observations of their own. Despite the lack of information available in the literature regarding this mode of dispersal, there is an overwhelming amount of anecdotal evidence of its frequency. Therefore, I must conclude that this may be a significant dispersal mechanism, at least for treefrogs in Southwest Florida. At the very least the mechanism needs to be rigorously examined, possibly through a randomized volunteer system where people can make and record similar observations to what I have done within this manuscript. If the mechanism is confirmed, an experimental project could be designed to determine the likelihood of transported individuals to persist in their new habitat and whether persistence varies by species. Finally, population genetic investigations could be used to elucidate how influential this type of dispersal mechanism is on the various populations.

Observations of a Remnant Population of the Critically Endangered Hylid Frog *Isthmohyla rivularis* on the Monteverde Cloud Forest Preserve, Costa Rica

Global amphibian declines are recognized as a very serious, wide-spread phenomenon, with over 40% of all amphibian species at risk of extinction and as many as 120 species that may have gone extinct in recent decades (IUCN 2012; McCallum 2007; Stuart et al. 2004). Some regions have experienced more decline than others, and many amphibian populations in Central and South America have decreased. The implications of these declines are compounded by the biodiversity in this region, which is home to approximately half of the amphibian species in the world (Stuart et al. 2008). Costa Rica, with its size considered, has one of the highest diversities of amphibians in the world and the percentage of threatened species is comparable to global levels with 31% either extinct (1%), critically endangered (12%), endangered (12%) or vulnerable to extinction (7%) (IUCN 2012).

A troubling aspect of many of these declines is that they have occurred in protected areas. The Monteverde Cloud Forest Preserve (MCFP) in Costa Rica consists of 4,025 hectares of pristine forest, and is part of a larger complex of 50,000 hectares of protected forest (G. Alvarado pers. comm.) yet even this area has experienced severe population declines and extinctions of amphibians (Pounds 2000). A well-known example is the charismatic golden toad (*Incilius periglenes*), listed as exctinct by

FIG. 1. Study stream on the Atlantic slope of the Cordillera Tilarán, Costa Rica, within the Monteverde Cloud Forest Preserve. This stream typifies the lower montane cloud forest in which the recently rediscovered local population of *Isthmohyla rivularis* occurs, and where observations and stream surveys were conducted.

the IUCN (2012). A study by Pounds et al. (1997) in the MCFP revealed that ~40% of the species formerly occurring at their study sites were not detected, and were considered by some to have gone locally extinct (Wheelwright 2000).

Amphibian declines have not occurred evenly across taxa in the New World. For example, approximately half of all species in the families Bufonidae (55%) and Leptodactylidae (47%) are threatened as are 27% of Hylidae species (Young et al. 2004). Within the family Hylidae, the genus Isthmohyla is endemic to mountainous regions of Central America and has a high proportion of threatened species, with over half of the species threatened and 7 of 15 species critically endangered (Stuart et al. 2008). One such species, *Isthmohyla rivularis* (Taylor 1952) has experienced severe population declines throughout 80% or more of its range in Costa Rica and was thought to have disappeared from Panama (Solís et al. 2008), although recent survey efforts by Hertz et al. (2012) have documented *I. rivularis* in Panama. This species was once abundant on the MCFP but populations declined sharply and it was considered locally extinct by some until 2007 when it was rediscovered (Solís et al. 2008). The cause of the decline in this species, particularly populations in and near the MCFP is not known. However, there are several hypotheses regarding possible factors of declines worldwide that may also be pertinent to the current situation in the MCFP. These factors include pollution (Davidson 2004), climate change (Pounds et al. 2006) and disease (Lips et al. 2006). Synergistic effects of these various factors are also possible (Pounds and Crump 1994). Other factors such as habitat loss (Gallant et al. 2007), exotic species (Kats and Ferrer 2003), and over harvest (Warkentin et al. 2009) seem to have little applicability to species in the MCFP.

Although this species was once common, very little is known about its breeding ecology. The rediscovery of this species presents a rare opportunity to investigate the ecology and abundance of a critically endangered species at the location of its reappearance within the Monteverde Cloud Forest Preserve.

Materials and methods.—Isthmohyla rivularis is a small, relatively drab, yellow-tan to gray tree frog that is associated with fast-flowing, highland streams in which its tadpoles develop (Duellman 2001; Savage 2002). The chorusing behavior of *I. rivularis* is generally described as occurring in herbaceous vegetation and shrubs at the margin of fast-flowing streams and tadpoles are described as using an oral disk to cling to rocks in the stream (Duellman 2001; Savage 2002; Stuart et al. 2008). The egg deposition and amplexus of this species have not been described.

We conducted a stream survey during 13–15 June 2011 on the MCFP at an area within the preserve known as El Valle (Fig. 1). The site is on the Atlantic slope of the Tilarán Cordillera at an elevation of 1350 m and is comprised of lower montane wet forest (Holdridge 1967). Surveys took place over three consecutive nights and consisted of 42 person-hours during the suspected peak of breeding activity (Savage 2002). Surveys began between 1815 and 1900 h and lasted until 2015 to 2130 h. Precipitation, temperature, and humidity were recorded at a local automated weather station operated by the MCFP staff. The lengths of stream surveyed on June 13, 14, and 15 were 290, 303, and 262 m respectively, and these lengths were consecutive and non-overlapping. We conducted surveys by slowly walking the stream, visually inspecting vegetation for the presence of frogs, and listening for advertisement calls. Calling males were then located and captured. Because this species is critically endangered, we did not feel tissue or voucher specimens were warranted. However, we used morphological and call characteristics to positively identify the species in the field. Our field identification was corroborated by MCFP staff biologists (A. Pounds, pers. comm.). We recorded snout–vent length (SVL) and mass before returning each frog to the flagged capture site. The following day, the distances between calling males, height at calling positions, and distances from the stream edge were determined with a meter tape.

In addition to encounter surveys, we used a bank-to-bank belt transect method (Welsh and Ollivier 1997) to survey 303 m of stream for tadpoles. At 10-m intervals the wetted width and the depth at ¼, ½, and ¾ stream widths were measured to determine stream profile, and we characterized the predominant water class (e.g., riffle, rapid, cascade, glide, pool) (Kaufmann and Robison 1998). The predominant substrate of the stream was noted (e.g., bedrock, boulder, cobble, gravel, sand, mud, organic debris). At each 10-m interval, a 1-m belt transect was searched for the presence of *I. rivularis* tadpoles by carefully disturbing the substrate while visually inspecting for the presence of tadpoles, and using a net to collect any dislodged tadpoles swept downstream.

FIG. 2. Adult male *Isthmohyla rivularis* found in situ, representing the typical advertisement calling site on plant stems, encountered in the Monteverde Cloud Forest Preserve, Costa Rica.

Results.—Climatic conditions during our sampling period were similar to the monthly mean for this site. The daily precipitation during the study period was 3.6, 31.2, and 8.6 mm (June 2011 mean = 9.3 mm) while the mean temperature for each day was 17.6, 17.4, and 16.5°C (June 2011 mean = 17.4°C). The mean temperature for the survey hours each night was 17, 16, and 16°C. The mean humidity during the survey hours each night was 87, 86, and 86% (MCFP, unpubl. data).

Fourteen chorusing males were encountered and 12 were captured during 42 h of survey effort (0.3 frogs per person-hour). Males ranged in size from 30.0 to 33.7 mm SVL and 1.10 to 3.00 g. Of those located, the distances between adjacent chorusing males ranged from 0.1 to 160.9 m with a mean of 73.0 m (SD = 60.3 m). Although not indicated by the mean, six of the chorusing males (3 pairs) were found within 2 m of one another. Calling positions ranged from 0.0 to 10.4 m from the stream edge with a mean of 2.2 m (SD = 2.7 m). They were perched from 0.2 to 1.1 m above the ground with a mean of 0.8 m (SD = 0.6 m). All frogs were found perched on stems (see Fig. 2), mostly the stems of small dicot trees and shrubs (N = 10), but were also encountered on aroid and fern stems (N = 2), but never on leaves.

The section of stream surveyed for tadpoles had a mean width of 2.3 m. The mean depth at the center was 0.2 m and the mean depth at ¼ and ¾ widths was 0.1 m. The stream classes at transects were as follows: riffle (57%), cascade (15%), rapid (12%), glide (12%), and pool (4%). The stream substrate was predominantly cobble with areas of boulders and coarse woody debris. No *I. rivularis* tadpoles were encountered; however, we noted the presence of various stream invertebrates.

Discussion.—Our findings quantitatively support anecdotal accounts of *I. rivularis* calling near the margin of streams and at relatively low perch heights (Duellman 2001; Savage 2002; Solís et al. 2008; Stuart et al. 2008). We also observed one frog calling 10.4 m from the stream margin, which supports anecdotal comments by Duellman (2001) and Savage (2002) that this species utilizes habitat beyond the immediate proximity of the stream. Future research could include focal studies to determine if males initiate chorusing away from the stream and then move toward the stream edge or if they chorus at constant distances from the stream throughout the night. Stems appear to be the preferred perch location, as all of the chorusing males were calling from stems and never leaf surfaces. Observations reported by Hertz et al. (2012) on calling male *I. rivularis* in Panama were similar, with 3 of 4 males encountered being found calling from stems. Due to their perch site selection, calling males were often very well concealed within the interior of each plant. Taylor (1952) described being unable to locate calling males until he removed nearly all the vegetation along 200 m of the stream margin forcing frogs to call from remaining clumps of vegetation. Hertz et al. (2012) also found that calling male *I. rivularis* were well-concealed within dense brush. Consequently, we located all male frogs by cuing in on their advertisement calls and none were located by visual encounter. This suggests that females may be much more difficult to locate. Future work might include intensive visual searching among woody plant interiors to determine if females utilize microhabitats similar to males.

The distances between chorusing males were extremely variable and did not seem to show any trend. Characterization of streamside vegetation might allow the determination of relationships between distribution and microhabitat differences. Our focal observations and an anecdotal account (G. Alvarado, pers. comm.) indicate that it is not uncommon for *I. rivularis* to call in clusters of two or more individuals within a few meters of each other. These previously unavailable observations improve our understanding of the microhabitat use and spatial distribution of calling male *I. rivularis*.

Our results also provide a rudimentary estimate of the relative abundance of this recently rediscovered local population of a critically endangered species. Our survey for tadpoles took place during the supposed peak breeding period (Savage 2002), and both Duellman (2001) and Savage (2002) report that historically tadpoles of *I. rivularis* at all stages of development could be found year round. Consequently, our failure to detect tadpoles may support an estimate of low population density at this site relative to historical abundance (Savage 2002). Continued research on this species is warranted including monitoring of this local population.

The scale of this project was limited spatially and temporally. However, the breeding ecology of *I. rivularis* likely does not vary greatly from site to site and the details we provide on calling site, microhabitat, and distribution along the stream margin should be useful in future survey efforts. To combat the spatial and temporal limitations of this work, future surveys for this species should be completed throughout its historical predicted range including sites where it was formerly documented (e.g., study sites of Pounds et al. 1997) as well as within areas modeled

as having high likelihood of harboring relictual populations (García-Rodríguez et al. 2012). Surveys should also be conducted at varying times of the year. Further aspects of this frog's breeding ecology need to be described including details on amplexus and egg deposition. Additional habitat characterization should be completed in order to improve conservation efforts for this critically endangered species and inform land management practices in areas where it is found. These efforts would not only improve the conservation of *I. rivularis* but potentially other stream breeding amphibians. Finally, explorations of current factors and historical causes of declines in the MCFP might be informative to local conservation efforts, as well as shedding light on other declines.

Acknowledgments.—We thank the Murdock Charitable Trust for partial funding of this project (Life Science Research Grant #2009260). We are grateful to Geiner Alvarado, Osvaldo Vargas, and Sergio Vargas of the Monteverde Cloud Forest Preserve (MCFP) for their assistance with the stream survey, for logistical support, and for sharing their knowledge. We also appreciate the assistance with logistics and permits provided by Christian Mena and Yoryineth Mendez (MCFP). Carlos Hernandez (MCFP) graciously supported our research within the reserve he manages. We would like to thank Jessie Cossel, Rebecca Cossel, Joy Warrington, and Alicia Hedrick (NNU) for their help with survey efforts. This manuscript was much improved by comments provided by Alan Pounds (MCFP), an anonymous reviewer, and *HR* editorial staff. Our work was conducted under Ministerio del Ambiente, Energia y Telecomunicaciones Scientific Passport #04698. Animals were released unharmed after sample collection, photography, and measurements. We complied with the Animal Care guidelines during this research and obtained all necessary state, federal, and international permits.

Amphibian Diversity on Floating Meadows in Flooded Forests of the Peruvian Amazon

Floating meadows are often associated with Amazonian white-water flooded forests (varzea), where they grow between the tree line and open-water. Seasonal flooding in varzea results in an unstable forest floor for terrestrial species. However, floating meadows may offer a refuge for some species that would otherwise be displaced by rising water. Floating meadows consist of herbaceous water plants that begin growing at the end of the low water period, taking root in the waterlogged soils of river, channel and lake banks. As the water rises, some plant species grow rapidly upwards, others become free-floating and grow horizontally, expanding the surface area they occupy (Junk 1970, 1997). As water levels begin to recede, currents and rainfall can dislodge sections of floating meadows to create rafts that are then transported via the river current.

The importance and diversity of floating meadows has been highlighted for several taxa (Goulding et al. 1996; Junk 1997; Schiesari et al. 2003; Dias et al. 2011; Ferreira et al. 2011), yet studies focusing on amphibian use of floating meadows are relatively scarce. Junk (1973) found that amphibians were rarely encountered on floating meadows. However, methodology was not provided by Junk (1973), and if nocturnal surveys were not undertaken, amphibians were unlikely to have been adequately sampled. Carrying out specific amphibian surveys, Hödl (1977) found 15 anuran species on floating meadows and concluded that this habitat was a potential breeding site. Hoogmoed (1993) published a list of the herpetofauna known to occur on or near to floating meadows in Suriname, Bolivia, and Brazil, adding to Hödl's (1977) list. This research brought the total number of amphibian species recorded on floating meadows to 26 (Hoogmoed 1993). On the Solimoes River, Schiesari et al. (2003) observed 42 individuals comprising eight anuran and one caecilian species, all on floating meadow rafts. They highlighted the importance of rafts of floating meadow vegetation as dispersal vectors for fish and potentially also for amphibians (Schiesari et al. 2003). In a preliminary study of only 18 days, Upton et al. (2011) found 16 anuran species on floating meadows. The amphibians recorded on floating meadow habitats to date are listed in Table 1.

This paper aims to: 1) Update the current list of amphibians found on floating meadows in Peruvian varzea flooded forest, and 2) update the information on reproductive habitat use provided by Hödl (1977), which showed evidence of reproductive behavior on the floating meadow habitat (see Hödl 1977; Fig. 3, Table 1).

(4.893256°S, 74.355526°W). The Pacaya-Samiria National Reserve is one of the largest varzea forests in western Amazonia spanning over 20000 km^2 between the confluence of the Ucayali and Marañon Rivers.

Data collection.—Preliminary data for this study were collected in May and June 2009, with more extensive surveys conducted from March to October 2012. Most surveys were carried out at night from 1800–2400 h, with some daytime searches between 1400–1700 h.

The floating meadows surveyed were located in the Samiria River basin at PV1 Shiringal, PV2 Tacshacocha, Huishto Cocha, and PV3 Hungurahui. These sites cover a small proportion of the Samiria River Basin, which spans a wide area; however, they were chosen as they have varying levels of disturbance by local fishermen and tourism. At each site, surveys were conducted across all river systems, in both the main Samiria River and in adjacent channels and lakes. In total, 221 surveys were conducted, 52 in 2009 and 169 in 2012. The surveys in 2012 were split as follows: 71 in lakes, 60 in channels, and 38 on the main Samiria River. Around the lake edges, floating meadow surveys were conducted at 100-m intervals. Within the channel and main river, less floating vegetation was available to survey, so all sections were surveyed at least once. A 10-m boat with outboard motor was slowly driven into the floating meadow vegetation, causing it to part on either side of the boat with the aim of reducing disturbance. On each sampling occasion, an area of 2 m on either side of the boat (50 m^2 in total) was searched for fifteen minutes. During this time, all frogs encountered were captured and placed in individually marked pots. Time of capture, species, behavior (e.g., calling male) and location (including plant species and height above water), were recorded. All surveys were completed with one local field guide, one biologist, and three or four student volunteers. To locate frogs at night, one main flashlight was used by either a guide or the biologist (CB2-L1 Clubman Deluxe, LI-ION 9.2AH half-million candle power); all students used smaller flashlights such as the Petzl Tikka to search. Species identification was undertaken using several field guides (Ouboter and Jairam 2012; Duellman 2005; Bartlett and Bartlett 2003; Rodriquez and Duellman 1994). Although identification of Amazonian amphibians can be very difficult, many of the species observed on floating meadows are distinctive and can be quickly identified in the hand using identification guides. Voucher specimens were not taken as the collection of specimens from within this protected reserve was prohibited under the permit and authorization being used (Resolucion Jefatural No 005-2013-SENANP-JEF).

Data analysis.—To analyze microhabitat use, the data were separated into the four main genera: *Dendropsophus, Hypsiboas, Scinax,* and *Sphaenorhycnhus.* Kruskal-Wallis tests were then used to determine if there were significant differences in the median calling heights among species in the same genus.

RESULTS

Nineteen amphibian species and 1090 individuals were recorded on the floating meadow habitat representing four families (Table 2). Six species have not been previously recorded on floating meadows: *Dendropsophus leali, Osteocephalus taurinus, Scarthyla goinorum, Scinax garbei, Scinax pedromedinae,* and *Leptodactylus petersii.* Most of the species recorded on floating meadows were hylids (15) compared with only two leptodactylids, one bufonid, and one pipid. The most abundant species were *Dendropsophus triangulum* and *Hypsiboas punctatus* with 371 and 314 individuals, respectively. No other species was represented by more than 100 individuals. *Scarthyla goinorum* and *Scinax pedromedinae* were both represented by only two individuals while *Pipa pipa* and *Hypsiboas boans* were represented by just one individual each (Table 2).

The median height in which amphibians were found and the most commonly used (over 50% of encounters) plant species are presented for all species observed (Fig. 1, modelled after Hödl 1977, figure 3). One species, *Pipa pipa,* was found swimming at the water surface; all others were on the floating meadow or adjacent emergent vegetation. All leptodactylid and bufonid species were most often found on Water Lettuce (*Pistia stratiotes*), a species that floats on the water surface. *Paspalum repens* was the most commonly used plant species on the floating meadows and also the most abundant in the survey area. Only in *Sphaenorhychus* were there significant differences in perch height between species (Kruskal-Wallis chi squared = 16.62, $P < 0.05$, df = 2), with *S. carneus* occupying lower heights than *S. lacteus.* Calling males,

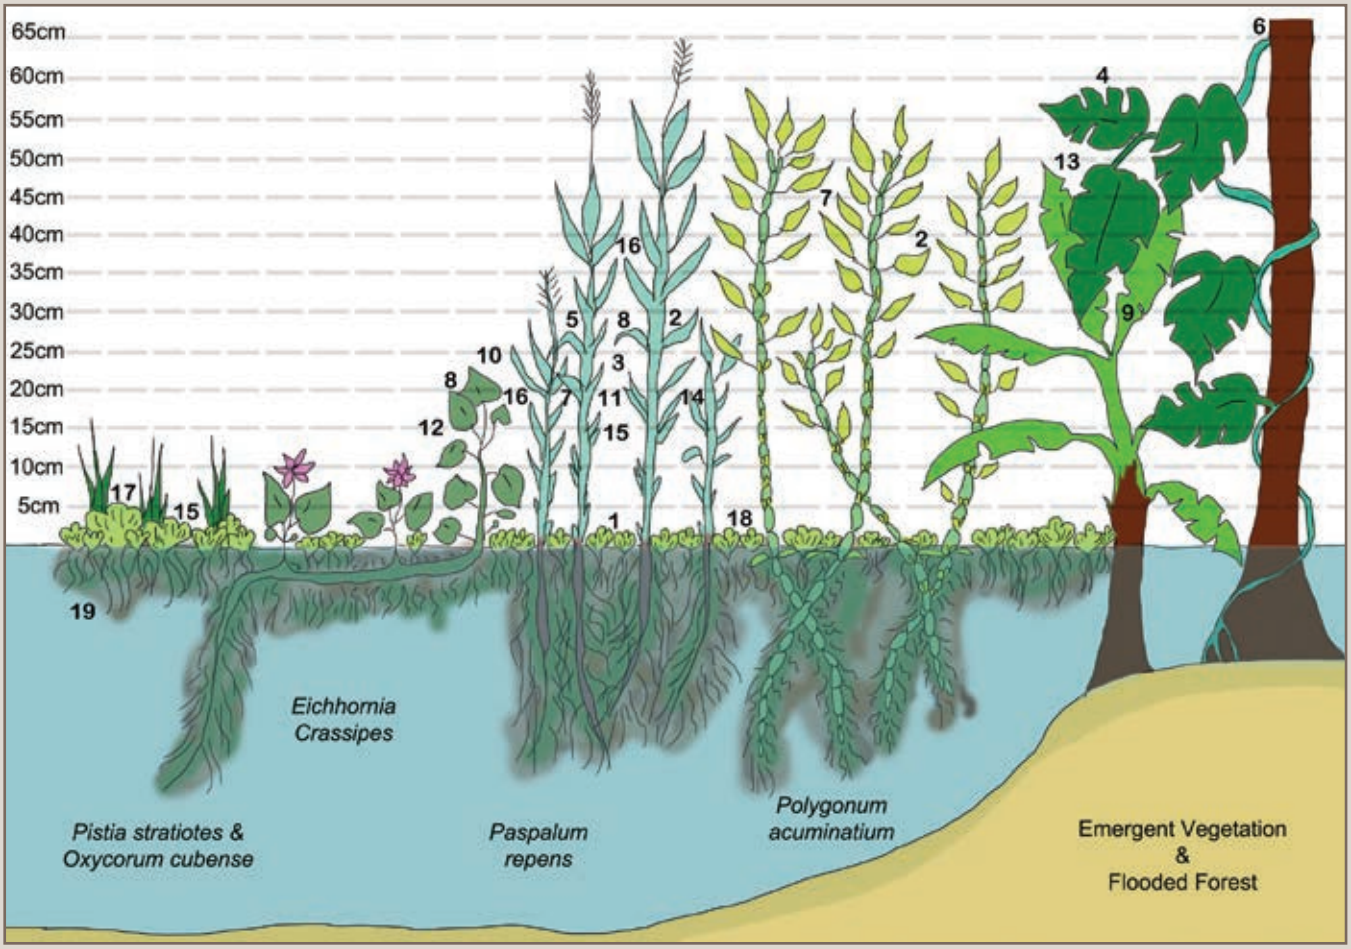

FIG. 1. Anuran species found on floating meadows, the most common plant species on which they were found, and the median height at which they were found. 1) *Rhinella marina* 2) *Dendropsophus haraldschultzi,* 3) *Dendropsophus leali,* 4) *Dendropsophus rossalleni,* 5) *Dendropsophus triangulum,* 6) *Hypsiboas boans,* 7) *Hypsiboas lanciformis,* 8) *Hypsiboas punctatus,* 9) *Osteocephalus taurinus,* 10) *Scarthyla goinorum,* 11) *Scinax garbei,* 12) *Scinax pedromedinae,* 13) *Scinax ruber,* 14) *Sphaenorhynchus carneus,* 15) *Sphaenorhynchus dorisae,* 16) *Sphaenorhynchus lacteus,* 17) *Leptodactylus leptodactyloides,* 18) *Leptodactylus petersii,* 19) *Pipa pipa.*

gravid females, and juveniles were all found on floating meadows, although only for hylids (Table 2, modelled after Hödl 1977). Calling males were observed for 11 of the 15 hylid species while ten species were represented by juveniles and six represented by gravid females. Leptopdactylids were only represented by adults, as were *Rhinella marina* and *Pipa pipa*.

DISCUSSION

Hylids were the most frequently encountered family on the floating meadows. The two most common species, *Dendropsophus triangulum* and *Hypsiboas punctatus*, are either rare or absent from the adjacent terrestrial habitat (pers. obs.), highlighting the importance of floating meadows for some hylid species. Other species were only represented by one or two individuals. One example is *Pipa pipa*, a fully aquatic species that is rarely encountered on land; this individual was caught swimming at the surface of the water. The floating meadow root system potentially offers refuge and cover to aquatic species such as *Pipa pipa*.

Few leptodactylids and bufonids were observed on the floating meadows, as these species are usually terrestrial and are regularly encountered on the forest floor within the leaf litter (Allmon 1991) or on river banks (Bartlett and Bartlett 2003), and it is therefore possible that frogs in these families are only using floating meadows as a refuge during high water periods. In both 2009 and 2012 the water level in Pacaya-Samiria exceeded all records from the last 100 years (Bodmer et al. 2012). During these high water periods up to 95% of the reserve can be inundated, with water levels reaching a depth of several meters within the forest. This reduced availability of terrestrial habitat may have displaced some individuals onto floating meadows.

Hödl (1977) noted frogs showing call site segregation, with most species associated with specific plant species. Calling males were regularly observed on the floating meadows in this study, with most species calling from a certain plant species at similar heights. For example the three *Sphaenorhynchus* species called from significantly different heights on *Paspalum repens*. Anuran morphology may influence plant choice, for example, the small *S. carneus* was sometimes observed calling from *Oxycoryum cubense*, a small grass species. Male *S. carneus* are usually between 15–18 mm and females 22–23 mm SVL, compared to *S. lacteus* males which are 26–29 mm and females 36–40 mm SVL (Rodríguez and Duellman 1994). The latter, larger species may be unable to physically climb up on this smaller grass species. Other species that showed preference for certain plants includes *D. triangulum*, which was most commonly found on *Paspalum repens*, and

H. punctatus, which was found on either *Paspalum repens* or *Eichhornia crassipes*. This is consistent with Hödl's (1977) findings in which *D. triangulum* and *H. punctatus* were both observed on plants in the genus *Paspalum*.

Hylids may potentially be using floating meadows for breeding, as calling males, gravid females, egg masses, and newly metamorphosed juveniles of twelve species were observed. These findings are consistent with Hödl's (1977) observations of calling males and pairs in amplexus on floating meadows. Many hylids are arboreal and are documented to move from higher strata to breed in temporary or permanent pools of water in the terrestrial habitat (Rodríguez and Duellman 1994; Bartlett and Bartlett 2003; Dodd 2010). However the flooded forest in the Pacaya-Samiria Reserve can be inundated for up to 6–9 months a year, resulting in an unstable terrestrial habitat. Additionally, the draining of floodwaters occurs rapidly, with fluctuations of up to 30 cm a day. Thus, temporary pools are only available for short periods, if at all.

Floating meadows may be a more stable habitat, available for the 6–9 months that the terrestrial habitat is flooded, and also offers an opportunity to study species that are not often encountered within the terrestrial habitat. In addition, floating meadows may offer an important refuge for other anuran families during extreme flooding. Marked oscillations in annual water levels are becoming more common due to climate change (Bodmer et al. 2012). The availability of floating meadows is dependent on the water level. Therefore it will be important to further elucidate the role of floating meadows in maintaining amphibian diversity in flooded forests as seasonal flooding becomes more extreme.

Acknowledgments.—This research is supported by the University of Kent alumni scholarship, which is fully funded by alumni of the university. Thanks to Richard Bodmer and Richard Griffiths for support and guidance. Thanks to the Pacaya-Samiria National Reserve Authority (SERNANP) (Resolucion Jefatural No 005-2013-SENANP-JEF) for authorization and permission to conduct this research, and to the following for helping to fund this project and for logistical support: Durrell Institute of Conservation and Ecology, FundAmazonia, Wildlife Conservation Society, Earthwatch Institute, Operation Wallacea and Operation Earth. Finally we thank all the Earthwatch, DICE, Operation Wallacea, and Operation Earth volunteers as well as Sophie Rost, Hannah Conduit, Lizz Willott, Abbie Parke, Elizabeth Wells, and Eric Woebbe.

Factors Influencing Habitat Occupancy of the Endangered Barrier Range Dragon (*Ctenophorus mirrityana*: Agamidae)

The habitat requirements of many reptile species worldwide are poorly understood. Yet for threatened and endangered species, this lack of knowledge has the potential to limit the success of species recovery and conservation programs. Further compounding this limitation of knowledge is that the collection of adequate datasets is usually not possible given small population sizes of threatened and endangered species.

Formerly recognized as an outlying population of Tawny Crevice Dragon (*Ctenophorus decresii*) due to similarities in dorsal color pattern and adjacent distribution, recent taxonomic revision of the *C. decresii* complex has revealed that a new species, *C. mirrityana* (Barrier Range Dragon), forms the New South Wales (NSW) populations (McLean et al. 2013). The Barrier Range Dragon is a small agamid measuring 8 cm (snout–vent length) that occurs in rocky hills and gorges of western NSW and is known from only three locations: Mutawintji National Park (Swan and Foster 2005), Koonaberry Mountain (one museum specimen), and the largest known population at Silverton (Sass and Swan 2010). Prior to the discovery of the Silverton population, the species had a highly restricted distribution (Sadlier and Pressey 1994) with the area of known occupancy being less than 1200 ha^2. With the likelihood of the degradation of these habitats by introduced herbivores such as feral goats and the potential risk of population loss due to a stochastic event such as fire, the former NSW *C. decresii* populations were listed as Endangered under the schedules of the NSW Threatened Species Conservation Act 1995 (OEH 2014). With the discovery of the Silverton population, an opportunity to better understand the factors influencing habitat occupancy of this endangered agamid arose with both large numbers of individuals and a large area of occurrence.

The aim of this study is to develop an understanding of the factors influencing habitat occupancy of the Barrier Range Dragon, which can then be used to guide future research and aid in the development of a species recovery plan and conservation program.

Methods

Study area.—The Study Area is located near Silverton approximately 30 km NW of the city of Broken Hill in far western NSW and within the Broken Hill Complex Bioregion (Thackway and Creswell 1995).

Field surveys.—Field surveys were conducted over 6 days in November 2007 for a total of 171 person-hours. Survey teams were comprised of two persons each—an experienced herpetologist and an assisting ecologist. Each team completed transects that were conducted either on foot or with a vehicle slowly driven on tracks that dissected the study area (Blomberg and Shine 1996). While the detectability of this species is the subject of another manuscript currently in preparation, the latter method (by vehicle) was deemed the most successful given that individuals sit high on exposed rocks and are easily visible from a moving vehicle despite the small size of this species. Team members visually scanned areas of potential habitat using high-powered binoculars seeking active and inactive animals. Survey locations were only visited on one occasion to ensure that individuals were recorded only once.

Habitat variables.—Habitat variables were measured at a random subset of sites where the Barrier Range Dragon was present (N = 32) and absent (N = 32) (total of 64 quadrats). Given that specific habitat data for the Barrier Range Dragon were unknown, a range of habitat variables were measured at sites where the species was present and absent. These variables were chosen with consideration of the known and hypothesized ecological requirements of the Tawny Rock Dragon and other members of *Ctenophorus* (Gibbons and Lillywhite 1981; Stuart-Fox and Owens 2003; Swan et al. 2004; Osborne 2005a,b; NGHEnvironmental 2008; OEH 2014) and those known from other studies to have an influence in reptile presence/absence such as grazing and ground microhabitat (Hadden and Westbrooke 1996; Hecnar and M'Closkey 1998; Fischer 2004; Sass 2004). The presence of Gidgee Skinks (*Egernia stokesi*) or their scats was also recorded given that past studies have suggested a negative correlation between this species and habitat occupancy by Tawny Rock Dragons (OEH 2014). This resulted in a total of 18 habitat variables being measured (Table 1). These were measured using a 10 m x 10 m quadrat centered where each individual was first observed or in the case of absent sites, the quadrat was centred on habitat where individuals were not observed. Rock crevice width was measured rock to rock to ensure independent variables, regardless of the presence of scats which could influence crevice width.

Statistical analysis.—Habitat variables were examined to determine potential differences in habitat at sites where Barrier Range Dragons were present and absent. These were analyzed using non-metric multidimensional scaling (nMDS) ordination to create a visual representation of the relationships between each habitat variable (Minchin 1987; Clarke 1993). Ordinations were performed in two dimensions, with 100 iterations for each dimension to guard against dissolute explanation (Wilkinson 1989). nMDS was chosen for the analysis because it is considered more robust to non-lineal effects when compared to other ordination techniques (Minchin 1987). Similarities between present/absent sites were calculated using the Bray-Curtis similarity measure (Bray and Curtis 1957). One-way analysis of similarities (ANOSIM) was then performed to compare each site and the presence of Barrier Range Dragons (Minchin 1987) using a 0.05 level of significance.

Where differences were identified through ANOSIM and the calculated 'R' statistic, these were further examined using

SIMPER analysis. To facilitate interpretation of the nMDS, Spearman rank correlations were conducted between the scores of each dimension and the habitat variables. This procedure allowed determination of the variables that were most correlated with each of the two dimensional nMDS axes and likely to be variables of importance to the presence of the Barrier Range Dragon.

Results

All Barrier Range Dragons recorded were located on the main ridge systems that comprise the study area. The majority of these were found on the flatter tops of ridges (67%) with the remainder on the downslope away from the ridge top and in one case, in a creek gully. Barrier Range Dragons were more often recorded on an aggregation of rocks (89% of records) than a single, isolated rock. Along existing vehicular tracks that traverse the study area, 15 Barrier Range Dragons were observed displaying or basking on the rock spoil.

The nMDS ordination revealed that two dimensions were sufficient to provide a reliable representation of the 16 site-specific habitat variables specific to microhabitat analysis (stress value = 0.19). Habitat variables could not be separated based on a visual inspection of the MDS ordinations where the Barrier Range Dragon was present or absent, however, a slight pattern appears to be emerging with some grouping in the absent sites. ANOSIM found a statistically significant difference between habitats where the Barrier Range Dragon was present/absent (global R = 1, $p = 0.027$). Further analysis using SIMPER revealed that the percentage cover of exposed rock outcropping contributed to 43% and percentage cover of rocks between 251–500 mm contributed to 14% of the differences in habitat.

Additional nMDS ordination of habitat variables where the Barrier Range Dragon was present, revealed that no particular pattern was evident in habitat variables. Habitat variables were correlated within each nMDS dimension using Spearman-rank correlations which found seven of the 16 habitat variables were significantly correlated to the first dimension, whilst three variables were significantly correlated to the second dimension using a 0.01 level of significance (Table 2).

Significant correlations with the first dimension were percent cover of ground vegetation, level of grazing, rock size (101–250 mm, 501–1000 mm, > 1000 mm), crevice width (51–100 mm) and the degradation of crevices. For the second dimension, the level of grazing, rock size (251–500 mm) and degradation of crevices were significant correlations. Interestingly, some overlap between variables across each dimension occurred. These were the level of grazing and the degradation of crevices which are contributing most to levels of habitat quality.

Discussion

A critical component of conservation and species recovery plans is an understanding of the habitat requirements of species and populations. This paper provides the first study of the factors influencing habitat occupancy of a recently described species, *Ctenophorus mirrityana*. Variables associated with the size and structure of rock outcropping and the level of grazing were found to have the greatest influences on the presence of this lizard.

The influences of rock size and crevice width confirm that the Barrier Range Dragon is a rock-obligate species and we suggest that it is likely to have discrete preferences for microhabitat structure. The results of this study provide a basis for further investigations on the influence of rock and crevice size, two variables likely to be particularly important for habitat restoration and the potential success of translocation.

A key threatening process for many species, the competition and habitat degradation by feral goats (*Capra hircus*) (OEH 2014) is of particular relevance to the Barrier Range Dragon. Feral goats have already been implicated in the degradation of outcrops for other rock obligates such as the Broad-headed Snake (*Hoplocephalus bungaroides*) (Murphy 1996) and the Centralian

Table 1. Summary of habitat variables measured within each quadrat.

Habitat variable	Details
1. Vegetation cover	Percentage cover of ground vegetation
2. Bare ground	Percentage cover of bare ground
3. Rock outcropping	Percentage cover of exposed rock outcropping
4. Fallen timber	Percentage cover of fallen timber
5. Level of grazing	Number of pats (feral or native) as a surrogate for the current grazing level
6. Rock size (0–100 mm)	Percentage cover of rocks between 0–100 mm
7. Rock size (101–250 mm)	Percentage cover of rocks between 101–250 mm
8. Rock size (251–500 mm)	Percentage cover of rocks between 251–500 mm
9. Rock size (501–1000 mm)	Percentage cover of rocks between 501–1000 mm
10. Rock size (>1000 mm)	Percentage cover of rocks greater than 1000 mm
11. Crevice width (0–25 mm)	Number of rock crevices between 0–25 mm wide
12. Crevice width (26–50 mm)	Number of rock crevices between 26–50 mm wide
13. Crevice width (51–100 mm)	Number of rock crevices between 51–100 mm wide
14. Crevice width (>100 mm)	Number of rock crevices greater than 100 mm wide
15. Degradation of crevices	Percentage of crevices with goat scats within
16. Gidgee skink or scats	Presence or Absence of Gidgee skinks or scats

18. Micro-landscape position	Position of the site (Slope, Flat, Gully)

Ranges Rock-skink (*Egernia margaretae*) (NPWS 2000), and given the level of significance in this study, the presence of rock crevices filled, or partially filled with goat scat is negatively contributing to habitat occupancy by *C. mirrityana*. In previous studies, grazing was suggested to be a key factor in determining the level and quality of habitat for many native species throughout the study area (NGHEnvironmental 2008). The impacts of heavy grazing by introduced herbivores are already known to be detrimental to reptile fauna. Hadden and Westbrooke (1996) found that reptiles were affected by changes in vegetation structure by overgrazing as this reduces microhabitat availability and habitat quality. Sadlier and Pressey (1994) identified that grazing was likely to adversely affect reptile species in the western division of NSW. While the results of our study suggest that feral goats are negatively impacting the Barrier Range Dragon, the absence of long-term data on the populations of Barrier Range Dragon and feral goats within the study area suggests that long-term research is required to gain a detailed understanding of these impacts.

Barrier Range Dragons are known from only two disjunct populations approximately 100 km apart; however, dedicated field surveys have not been undertaken in potentially suitable habitat elsewhere in the Barrier Range Complex Bioregion and this species might be more widespread than currently known. Conversely, the two known populations may be relicts from an historically wider distribution. Nonetheless, the previous endangered status applied to *C. decressi* under the NSW Threatened Species Conservation Act 1995 should apply to the recently described *C. mirrityana* in the absence of recent field surveys. Additionally, field surveys of potentially suitable habitat are recommended to determine the current distribution of this newly described species in order to adequately assess its current conservation status as it may qualify for listing as Critically Endangered under NSW legislation and nomination for listing under the Commonwealth Environment Protection and Biodiversity Conservation Act 1999.

For the first time, this study identifies the factors influencing habitat occupancy for Barrier Range Dragon. The development of a species recovery plan, a conservation and land management program, further research of the Silverton population, and field surveys of potentially suitable habitat across the Broken Hill Complex Bioregion are likely to provide a greater understanding of this newly described species, improve the long-term security of known populations, and allow for an adequate assessment of its current conservation status.

Table 2. Spearman-rank correlations coefficients of the 16 habitat variables against the two MDS dimensions. Significance at 0.01 is marked with two asterisks, 0.05 with one asterisk (two-tailed).

Habitat variable	Dimension 1	Dimension 2

Body Condition Factor Analysis for the American Alligator (*Alligator mississippiensis*)

The American Alligator (*Alligator mississippiensis*) is an integral part of the Everglades ecosystem (Kushlan 1974). Alligators affect and are affected by the landscape and changes in hydrology, which make them an excellent species for use in evaluating current Everglades restoration efforts (Jones et al. 1994; Rice et al. 2005; Mazzotti et al. 2009). The natural history and reproductive patterns of the American alligator are closely tied to its physical environment (Kushlan and Jacobsen 1990; Mazzotti and Brandt 1994) and information on alligators in the Everglades—survey data, capture data, blood chemistry, and reproductive statistics—has been collected since the 1950s (F. Mazzotti and K. Rice, unpubl. data). Historical information for the alligator provides a suite of useful life-history characteristics or population parameters (e.g., health and condition, nesting effort, growth rate and survival, and density) that can be used for restoration success criteria (Mazzotti et al. 2009). However, some life-history traits (e.g., absolute population density and survival rates) are difficult to measure accurately and it may take decades of data to identify trends.

Body condition, however, can be measured using simple indices and requires relatively fewer data for analysis, even between seasons (Lambert and Dutil 1997). If used properly, condition of an indicator species such as the alligator will produce a rapid assessment of population health and consequently the health of the indicator's ecosystem (Stevenson and Woods 2006). Condition can be defined as the "relative fatness of [an animal]. . . . it is a measure of how well that animal is coping with its environment" (Taylor 1979). Condition indices have been used for a range of organisms (Reyer and Bättig 2004; Karraker and Welsh Jr. 2006; Stevenson and Woods 2006) as indicators of ecosystem health and have the added benefit of being a non-destructive and non-invasive method for evaluating health of ap opulation. Condition index, or condition factor, is a function of skeletal length and a volumetric measurement and has been used most frequently in fisheries literature, where it has become deeply entrenched as a research paradigm (Cone 1989). This study evaluates condition indices for the American alligator and recommends the appropriate model for use in applications such as evaluating management or restoration

Study area.—Data for this study were collected from six units within the greater Everglades ecosystem of south Florida, USA (Fig. 1): Arthur R. Marshall Loxahatchee National Wildlife Refuge (LOX), Water Conservation Area 2 (2A), two sites in Water Conservation Area 3, North (3AN) and South (3AS), and two sites within Everglades National Park–Shark Slough (ENP-SS) and the estuarine (ENP-Est) areas located near Flamingo. All sites are freshwater except ENP-Est, which is brackish. All units are managed separately for hydrology (different average annual water depths), which affects the prey base and condition of alligators between units, making the Everglades an excellent system to compare possibly subtle condition changes within different areas of an ecosystem.

Methods.—We captured alligators (N = 384) occupying marsh only (no canals) in October and March from 1999 to 2002 and made efforts to catch approximately equal number of animals from each area per capture event. We did not capture alligators <0.5 m total length (TL), as juvenile growth rates are extremely variable (Brandt 1991), which would increase confounding variation to the analysis, particularly if condition differences were small between units. We measured the following morphometric variables to the nearest 0.1 cm (Zweig 2003): head length (HL), snout–vent length (SVL), TL, right hind foot length (RFL), neck girth (NG), tail girth (TG), and chest girth (CG), and measured body mass (BM) with a spring scale to the nearest 0.1 kg. We sexed alligators and released them at their original capture sites. We excluded animals with deformities or wounds that would affect measurements.

Using Web of Science (http://www.isiknowledge.com), we searched scientific literature databases using the words

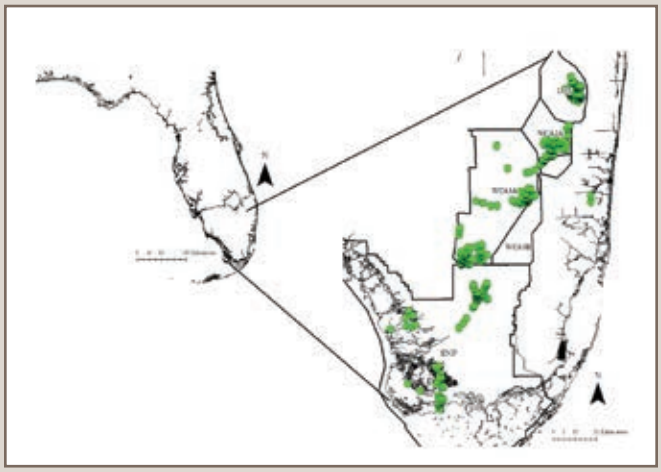

FIG. 1. Capture areas in south Florida within Everglades wetlands core. Green dots represent alligator capture sites from October 1999 to March 2002 (N= 395). ENP-Est = Everglades National Park-Estuaries, ENP-SS = Everglades National Park–Shark Slough, LOX = Loxahatchee National Wildlife Refuge, 2A = Water Conservation Area 2A, 3AN = Water Conservation Area 3A North, and 3AS = Water Conservation Area 3A South.

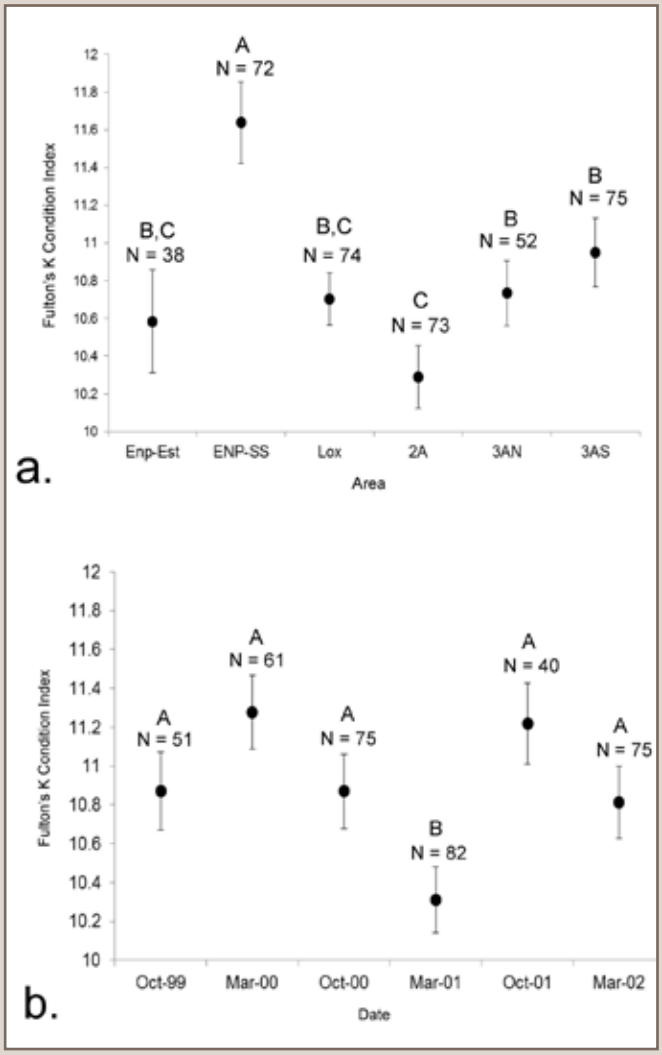

FIG. 2. a) Relative mean condition and standard error of alligators (N = 395) from six management units in the Florida Everglades from October 1999 to March 2002 using Fulton's K analysis. Site labels as in Fig. 1. Means with the same letter were not significantly different. b) Relative mean condition and standard error of alligators (N = 395) in the Florida Everglades by time from October 1999 to March 2002 using Fulton's K analysis. Means with the same letter were not significantly different.

"condition," "condition index," and "condition factor" to locate established methods of calculating condition for all types of animals. Condition is calculated using one straight-line measurement and one mass measurement, e.g., HL and BM. Tail girth in crocodilians is considered a proxy for mass (Hurlburt 1999) and is useful for large alligators that are difficult to weigh. We used the four length/mass combinations recommended by Zweig et al. (2004) to reduce error from measurement variation: HL|TG, HL|Mass, SVL|TG, and SVL|Mass, where "|" represents the combination of two morphometric variables used in calculating the condition index.

Condition indices should be independent of body size indicators or straight-line measurements, to separate the contribution of body size to mass from the contribution of fat stores, which more accurately reflect condition (Green 2001). We chose a Pearson's correlation threshold of 0.30 (any indices with $r > 0.30$ were eliminated) to ensure lack of correlation between body size and condition.

To test the ability of each index to distinguish differences in condition among units, between the sexes, or among time periods (i.e., model Condition index = Area + Sex + Date), we analyzed data with an analysis of variance (ANOVA) and Tukey's *post hoc* test for each index in aov (R Version 3.0, www.r-project.org, accessed 12 Apr 2013). Condition was also modeled with an ANCOVA procedure, glm (R Version 3.0, www.r-project.org, accessed 12 Apr 2013) as a separate indicator of condition.

To understand the biological significance of the ANOVA results, we constructed simulated data sets and tested them with the condition index ANOVA analysis above. This procedure provided background on the sensitivity of the analysis and condition indices, i.e., it indicated what percent difference in condition the analysis can detect. We simulated data sets using morphometric measurements that were identical to the original data set in standard deviation, but varied by the mean. There were 15 populations: 5 populations of 100 individuals with means identical to the original data; 5 populations of 100 individuals with a 5% increase in the mean; and 5 populations of 100 individuals with a 10% increase in the mean. We calculated condition of the modeled populations with the final two indices (Fulton's K and Relative K) and analyzed them using ANOVA and ANCOVA models as above.

We analyzed Everglades alligator capture data with the final recommended condition index (Fulton's K using HL and BM) to determine differences in condition among units. Units were grouped by significant differences in mean condition using Tukey's *post hoc* test.

Results.—We included the following condition indices from the literature in our analysis: ratio (Jakob et al. 1996), relative weight/mass (Wege and Anderson 1978), Fulton's K (Stevenson and Woods 2006), relative K (Le Cren 1951), ANCOVA (García-Berthou 2001; Le Cren 1951), and residuals (Green 2001), and calculated them for all four straight and mass measurement combinations, except Relative mass, which did not include a straight-line measurement and was calculated only for BM and TG (22 indices). We eliminated four indices for which the

Pearson's correlation between condition index and body length was >0.3 (Ratio HL|BM, $r = 0.94$; Ratio SVL|BM, $r = 0.95$; Fulton's K HL|TG, $r = -0.92$; Fulton's K SVL|TG, $r = -0.93$).

Eleven of 18 indices found significant differences in condition ($P < 0.05$) among units of the Everglades. Indices using SVL and HL combinations demonstrated significant differences among units, as did indices using BM and TG. The ANCOVA analysis includes only two significant differences out of four combinations. We chose Fulton's K as the best index to use, due to its ability to distinguish differences in condition among the most units.

The analysis of simulated data sets with Fulton's K did not detect differences in the data among simulated populations with the same mean and standard deviation, indicating that the model did not detect false differences in condition. Populations with the exact mean and standard deviation as the original data were consistently different ($P < 0.05$) than the simulated populations with the 10% increase in the mean. Populations with a 5% increase were not consistently different from the original data populations—only 84% of individuals were indicated by the model to be significantly different.

The Fulton's K index indicated that condition of alligators differed among water management units within the Everglades ($P < 0.05$; Fig. 2a). Alligators in the ENP-SS exhibited the greatest mean condition and their mean condition was significantly greater than that of any other area (Fig. 2). Alligators in areas 3AN and 3AS exhibited poorer condition than ENP-SS, but their condition was still greater than alligators in 2A, which had the lowest condition level of all areas. Mean condition of alligators in LOX and ENP-Est was less than only those alligators in ENP-SS. Condition of alligators in March 2001 was less ($P < 0.05$) than in March 2000 and October 2001, but no other differences between time periods were significant (Fig. 2b).

Discussion.—Condition indices can be a controversial method of comparing the general physical well-being of animal populations (Cone 1989; García-Berthou 2001; Green 2001; Jakob et al. 1996; Kotiaho et al. 1999; Krebs and Singleton 1993; Packard and Boardman 1988; Vila-Gispert and Moreno-Amich 2001). They are not appropriate for every situation and there are strict assumptions that must be met. However, if used prudently, we found that the Fulton's K condition index with HL and BM can be used to measure differences in the relative robustness among alligators or among two or more populations of alligators. Not only did the HL|BM combination of Fulton's K detect the most differences in condition between units (and reliably at a 10% condition difference), it has less stringent assumptions and can be used to compare across as well as within populations (García-Berthou 2001). It could serve as a standard for researchers comparing alligator condition among populations in Florida or across its range.

A shortcoming of Fulton's K is that it does not immediately provide a biologically meaningful number. The Fulton's condition score for this analysis ranged from 1.4 to 3.2, unlike an index like Relative Mass, where 1.0 is an alligator in normal condition and less than 1.0 suggests the alligator is in relatively poor condition (Stevenson and Woods 2006). To overcome a lack of biological meaning in Fulton K numbers, one could identify quartiles of the data and assign the bottom quartile as low condition, the middle two as average condition and the top quartile as good condition. Condition is a very fluid measurement that responds quickly to ecosystem perturbations, and condition indices can capture these short-term changes (Stevenson and Woods 2006). Water management practices and rainfall can change condition of animals in a relatively short amount of time. For the current study, ENP-SS alligators displayed the highest condition of Everglades alligators, but Dalrymple (1996) observed Shark Slough alligators to be in very poor condition five to six years earlier when water levels were higher. This highlights the advantage of using condition factor to assess the health of a population—its ability to use relatively small amounts of data and provide rapid assessments.

Information from the present study has been combined with environmental data to establish correlations among environmental variables and alligator condition and to determine the utility of the alligator as an indicator species for the Everglades (Fujisaki et al. 2009; Mazzotti et al. 2009). It was incorporated into the U.S. Army Corps of Engineers Comprehensive Monitoring and Assessment Plan for the Everglades and used for other crocodilian species (Mazzotti et al. 2012). It could also be used to compare crocodilian populations globally and has already been implemented in Belize for Morelet's Crocodile, *Crocodylus moreleti* (Mazzotti et al. 2012).

Acknowledgments.—We performed all captures under the auspices of the University of Florida's Institutional Animal Care and Use Committee guidelines. We would like to acknowledge A. Woodward for his careful review. Development and Validation of a Non-lethal Method for Monitoring Steroid Hormones in Plethodontid Salamanders

The analysis of steroid hormones is an important method for obtaining information about an animal's reproductive state or social status, as well as determining environmental factors that elicit stress responses. In large salamanders, blood sampling for steroid analysis has traditionally been conducted by either cardiac puncture (Church and Okazaki 2002; Lecouteux et al. 1985; Woodley 1994; Zerani et al. 1991) or decapitation (Specker and Moore 1980). In small salamanders with extremely low blood pressure and volume, however, samples are often taken from un-anesthetized and restrained animals (E. J. Crespi, pers. comm.). Although effective, these methods are likely painful and often lethal. In an effort to avoid lethal sampling or stressing endangered or sensitive animals, methods have been developed to extract steroids from tissues and bodily excretions, such as feces, urine, saliva, milk, ocular and respiratory secretions, and in the case of large spotted salamanders, ventral caudal scrapings (Homan et al. 2003; Rodrigo 2010).

Tail autotomization (self-amputation) is a defense mechanism employed by many salamanders to avoid predation. If sampled appropriately, tail tissue may be used to discern information about an animal's genotype, physiological condition, and ecological interactions. For instance stable isotopes, which may be used to study animal's diets, habitat use, and movement patterns, were recently measured from three species of Plethodontid salamander tail tissue (Milanovich and Maerz 2012). Variables such as species differences and amount of tail loss preclude making broad generalizations about the long-term health and fitness effects of autotomization (Bernardo and Agosta, 2005) but in an experimental comparison, brooding success was not different in tailless or control *P. cinereus* mothers (Yurewicz and Wilbur 2004). The purpose of the present study was to validate a non-lethal radioimmunoassay (RIA) for steroid hormones from autotomized tail tissue. To do so, we established seasonal hormone profiles for both male and female red-backed salamanders and compared them to plasma concentrations cited in the literature.

Materials and Methods

Sampling.—Striped and lead-backed (unstriped) Redback Salamanders (*Plethodon cinereus*) were collected during the spring (April), summer (July), and autumn (September) from hardwood forests in the immediate vicinity of the University of New Hampshire, Durham, New Hampshire, USA (43.14°N, 70.93°W), by carefully hand-searching under fallen logs**.** Only intact individuals with undamaged tails were collected, and the presence or absence of eggs was observed during the summer sampling. Gender and reproductive status of each individual was determined by "candling," as the animals are nearly transparent and their gonads and eggs are easily visible when backlit (Gillette and Peterson 2001). Inter-nares distance (the distance between nares at the tip of the snout), was further used to verify gender (Quinn and Graves 1999). Samples consisted of spring males (N = 5), summer males (N = 5), autumn males (N = 5), spring gravid females (N = 5), spring non-gravid females (N = 5), summer brooding females (N = 3), summer non-brooding females (N = 4), and autumn females (non-gravid, non-brooding, N = 5)**.** Salamanders were weighed to the nearest milligram and measured for total length and snout–leg length (to posterior of the hind legs) for rapid processing (Szuba et al. 2002). Within two hours of field collection, autotomization of tails was induced by pinching with a forceps approximately 6–9 mm posterior to the cloaca. Autotomized tails were weighed, and the tail section was flash frozen on dry ice and stored at -20 degrees for use in the assay. Following sampling, all animals were released at their original collection sites.

Extraction and Radioimmunoassay.—Tail samples (range 0.12–0.36 g, mean = 0.19 g, s.e.m. = 0.01) were finely minced with a razor blade and homogenized for three minutes using a Kinematica CH-6010 Kriens-LU tissue homogenizer (Brinkman Instruments, Westbury, New York) in 17 x 100 mm polypropylene tubes with phosphate buffered saline (PBS; 0.1M PBS + 140 nM NaCl, pH 7.0; 4:1 PBS: tissue). The homogenates were centrifuged (3,000g) for 10 min at 4°C and the supernatant was decanted for extraction. Steroids were extracted three times from the supernatant with ethyl ether (J. T. Baker, Phillipsburg, New Jersey) by vortexing for 10 seconds in 12 x 75 mm glass tubes, snap freezing in liquid nitrogen, and decanting. The samples

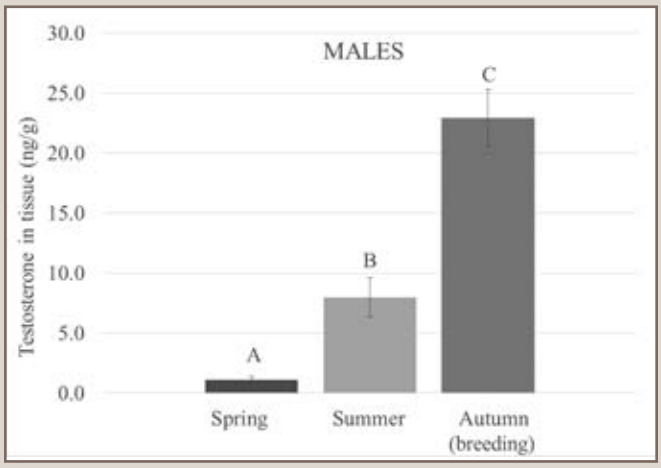

FIG. 1. Mean testosterone concentrations and standard errors for male *Plethodon cinereus* by season. Different letter superscripts indicate significant differences (P < 0.05)

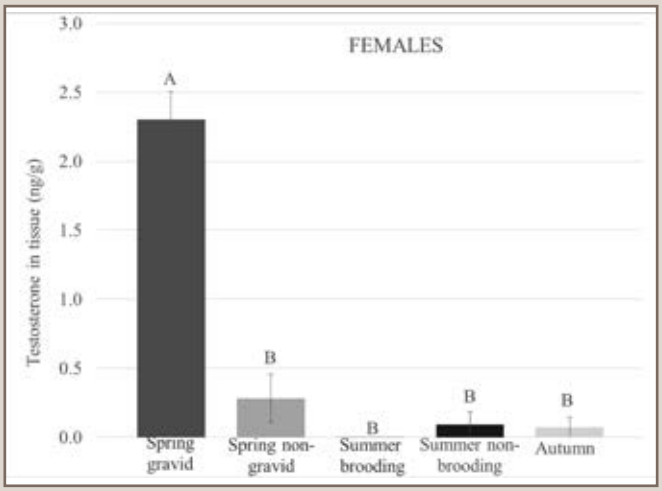

FIG. 2. Mean testosterone concentrations and standard errors for breeding and non-breeding female *Plethodon cinereus*, by season. Different letter superscripts indicate significant differences (P < 0.05).

were dried under a stream of nitrogen in a water bath at 37°C and frozen at -20°C prior to analysis.

The RIA protocol was modified from Sower and Schreck (1982). Extracts of homogenates were re-suspended in 200 µl assay buffer (PBS and 0.1% unflavored gelatin) vortexed vigorously for 10 sec, and duplicate aliquots (30 and 100 µl, male and females respectively) were assayed. Aliquots of testosterone (T) antisera (T3-125, Esoterix, Austin, Texas) diluted to a final concentration of 1:750, and 7400 dpm [1, 2, 6, 7- ^{3}H] testosterone (Perkin Elmer, Boston, Massachusetts) were added to the tubes, vortexed briefly and incubated for 90 minutes at room temperature. The tubes were placed in an ice bath, ice-cold charcoal/dextran [(100 ml 0.1M PBS; 1.0 g Norit neutral; Norit Americas, Inc. Marshall, Texas) and 0.1 g dextran (MW ~70000) (Sigma St. Louis, Missouri)] was added, and tubes were centrifuged (1,907 g) for 15 min at 4°C. The supernatant was decanted into vials, vortexed, and counted for 10 minutes (Beckman LS6500 liquid scintillation counter).

Cross reactivities of the antibody have been previously reported (Howell et al. 2003). Steroids with a cross reactivity >5.0% were: delta-1-testosterone (52%) and dihydrotestosterone (20%). Extraction efficiency, determined by the recovery of tritiated T from a homogenate of PBS and chopped tail sample (4:1), was 27.1%. Serial dilutions of homogenate extracts inhibited binding parallel to the standard curve. The intra and inter-assay coefficients of variation were 3.2% (N = 12) and 6.7% (N = 5), respectively and sensitivity of the assay was 4 pg/ tube.

Statistics.—Estimates for T concentration in the samples were calculated using AssayZap (BioSoft, GB-United Kingdom). Seasonal testosterone concentrations were log transformed and analyzed using ANOVA (SYSTAT 10; Systat Software Inc. Port Richmond, CA). Significant differences (P < 0.05) were identified with Tukey's post-hoc tests. Statistical outliers were determined using SYSTAT, and were retained in all analyses.

Results and Discussion

Seasonal T tissue concentrations for males differed significantly, increasing from spring to autumn (df = 2, F = 44.75, P < 0.03) (Fig. 1). Female tissue T levels were generally an order of magnitude lower than male's, except gravid females. Spring gravid females had significantly higher testosterone than any other female groups (df = 4, F = 4 2.49, P < 0.001), which did not differ from each other (P > 0.75 for all comparisons) (Fig. 2).

The results of this study indicate that steroid hormones can be extracted and measured from autotomized salamander tails and that seasonal concentrations reflect those previously measured in plasma. Church and Okazaki (2002) measured seasonal plasma testosterone concentrations from male *P. cinereus*, and similar to the present study, found highest and lowest concentrations from August–October and May–July, respectively. The elevated concentrations were concomitant with reported periods of increased aggression in this species and overlapped with mating activity (Sayler 1966; Wise 1995). Woodley (1994) also reported similar steroid expression and behavioral patterns in two other members of the family Plethodontidae (*Desmognathus ochrophaeus* and *Plethodon jordani)*. The plasma testosterone concentrations (296 ± 59.3 ng/ml Autumn; 9.8 ± 6.6 ng/ml Spring) reported by Church and Okazaki (2002) were approximately an order of magnitude higher than those found in the present study. These results are not unexpected, as gonadal steroids are typically synthesized and secreted into the systemic circulation, so plasma levels should be greater than the small amounts extracted from the tail vasculature. In females, significantly elevated T concentrations were only detected in gravid individuals, which is consistent with results found with *Salamandra salamandra*. In that species, plasma testosterone, estradiol and progesterone were all significantly higher in gravid compared to non-gravid females (Degani et al. 1997). It is possible that elevated testosterone concentrations in gravid females may be related to increased competition for a suitable nesting territory in which to lay eggs. Although few studies have compared seasonal steroid profiles between males and females, in *Pleurodeles waltl*, androgen concentrations (primarily T) were several fold higher than estradiol and paralleled increases in estradiol. Similar to the present study, androgen concentrations were considerably lower in females compared to males throughout the annual reproductive cycle (Garnier 1985 a and b).

Although steroids have been extracted from a number of animal tissue types (Hines et al. 1990; Taves et al. 2010), these procedures generally require lethal sampling, and comparisons to circulating plasma levels are unavailable. Corticosteroids are

often measured in salamanders as indicators of environmental and social stressors (Cooperman et al. 2004; Schubert et al. 2009). As plasma concentrations of these hormones can be relatively high (Schubert et al. 2009), autotomized tails may provide a non-lethal sampling method. Several methods are available for optimizing the extraction efficiency (Makin et al. 2010) prior to steroid analysis, and this may be necessary for species with low steroid concentrations.

Acknowledgments.—We thank Tim Breton, Michelle Scott, and Stacia Sower (UNH) for laboratory assistance and helpful suggestions to this manuscript. This research complied with the UNH Animal Care and Use Committee guidelines.

Duration of Marking Tags on American Alligators (*Alligator mississippiensis*)

Ecological studies of wildlife populations require individuals to be uniquely marked through the use of internal or external identification tags. Although marking tags are commonly used in ecological studies of the American Alligator (*Alligator mississippiensis*), little is known about tag retention in this species. Tagging techniques have been used extensively in research on crocodilians and have included passive integrated transponder (PIT) tags (Dixon and Yanosky 1993; Saalfeld et al. 2008), foot webbing tags (Rootes et al. 1991; Saalfeld et al. 2008; Temsiripong et al. 2006), and tail tags (Kushlan and Mazzotti 1989). Tagging crocodilians like the American Alligator and having them retain the tags may be more difficult than with other species as a result of the aquatic environments they inhabit, which have many underwater obstructions (e.g., sunken trees, logs, debris, etc.) that can catch on tags. Therefore, tag retention and durability may be compromised, which can be problematic for researchers. However, there has been little research to determine the magnitude of this problem.

We have developed a tagging technique for crocodilians that is similar in concept to the method used for fish species using the tags and tag applicator reported by Dell (1968). This method utilizes uniquely numbered and colored Floy® T-Bar anchor fish tags (Floy® Tag, Inc., Seattle, Washington, www.floytag.com; model FD-68B). The T-Bar anchor fish tag is constructed of heavy duty monofilament enclosed in colored vinyl tubing on which a unique number is printed. The tag measures 7.62 cm in length and 0.3 mm in diameter. Individual tags are inserted subcutaneously at the base of the skull with the Floy® Mark II rapid tag-fed applicator. The tag is inserted via an applicator equipped with a 14.5-gauge needle. The tags and applicator needles can be purchased in a variety of sizes. This improves the utility of this tagging strategy across a wide array of crocodilian size classes. This tagging strategy reduces further stress to an animal after capture, reduces the size of tags employed during research, increases the durability and longevity of tags, and provides a tagging strategy that is still as adequately useful, if not more so, than strategies that are currently in use. Our method uses tags that are much smaller in size, yet more visible than other types of tags that have been used on crocodilians. By employing this method and using fluorescent colored tags, researchers can easily spot tagged individuals, even when the majority of the animal's body is submerged beneath the water's surface. During nighttime searching, spotlighting causes the fluorescent tags to reflect light, yielding a visible tag even in low light conditions. This allows observers to determine the proportion of the population that is tagged and has the potential to be used in mark-resight studies on crocodilian species. However, it should be noted that in certain scenarios it is possible for tagged individuals to be overlooked. For example, areas of dense aquatic vegetation or poor visibility certainly have a negative effect on the visibility of these tags. Also, in the event that an individual is at an improper angle from or is facing an observer, or if eyes and tags are not properly exposed, visibility of tagged individuals may become compromised. The challenge of tag visibility is common among marking tags and this strategy is certainly no exception; however, T-bar anchor tag visibility is nevertheless enhanced in comparison to other tag types.

Tag failure can bias estimates of survival and population size (McDonald et al. 2003). Estimation of life-history parameters relies on the assumptions that the tags are retained for the duration of the study and that tagging has no adverse effect on the reproduction, growth, or survival of the individual (Fokidis et al. 2006). These assumptions are often considered when using marking tags on alligators; however, they have yet to be verified on the species. The objectives of the present study were to determine retention rates of three commonly used tags and one novel tag and determine the most cost- and time-effective tagging strategies.

Materials and Methods.—The present study was conducted in the southwestern portion of the American Alligator's range at Brazos Bend State Park (BBSP), located in Fort Bend County, Texas, USA. Brazos Bend State Park is approximately 32 km SW of Houston, Texas, USA. The park encompasses 1982 ha, with an eastern boundary of 5.2 km along the Brazos River on the southeast border of Fort Bend County. Of the 11 bodies of water located within the park, seven were included in this study: Elm Lake, Forty-acre Lake, Old Horseshoe Lake, New Horseshoe Lake, Pilant Lake, Creekfield Lake, and Hale Lake, all of which are inland freshwater lakes that are characteristic of the area.

A mark-recapture analysis of American Alligator populations was conducted using the mark-recapture methods outlined by Chabreck (1963). Alligators were captured through the use of several techniques (e.g., snake tongs, pole snares, hand capture, and swim-in live traps). Upon capture, individuals were restrained with duct tape. Sex of individuals ≥ 50 cm in length was determined using the cloacal examination method developed by Chabreck (1963). Sex of individuals < 50 cm was not determined due to the difficulty of using available methods in the field. The morphological measurement of total length (TL, cm; ventral tip of snout to tip of tail) was taken for each alligator with a flexible tape measure. Each captured individual was uniquely marked with a numbered and colored livestock ear tag (Allflex USA, Inc., Dallas/Ft. Worth Airport, Texas) that was inserted in the tail, a uniquely numbered Kemco ear tag (Ketchum Mfg. Co., Inc., Lake Luzerne, New

Table 1. Marking specifications and retention rates of American Alligators tagged with four types of marking tags during 2012–2013 in southeast Texas.

	T-bar anchor tags	Foot tags	PIT tags	Tail tags

York) that was placed in the webbing between two toes, and an individual MUSICC Chip PIT tag (AVID Identification Systems Inc., Norco, California; www.AvidID.com) that was inserted subcutaneously at the base of the tail. Additionally, individuals were marked using T-bar anchor tags inserted under the skin at the base of the skull. Daytime and nighttime visibility distances for the T-bar anchor tags were determined through the use of a Bushnell yardage pro 800 rangefinder (Bushnell Performance Optics, Lenexa, Kansas; www.bushnell.com). Tag visibility measurements were taken under multiple field conditions including at night from a boat (i.e., under conditions typically experienced during alligator surveys and capture events), at night on land, and during the daytime. Due to size limitations and morphology of young alligators, foot webbing and tail tags were placed only on alligators ≥ 50 cm TL. One year subsequent to the initial capture and tagging effort, individuals were recaptured to determine the retention of marking tags. In an attempt to eliminate bias in our estimation of tag retention, we captured all individuals, regardless of whether tags were visible. When tagged alligators were recaptured, they were measured again for TL and data on the presence or absence of tags was recorded. Chi-square analysis was used to determine if distributions of tag retentions differed among tag types at $\alpha = 0.05$.

Results.—In 2012 we marked 206 American Alligators (Table 1). Marked individuals ranged in size from 20.3 to 365.8 cm TL. In 2013 we recaptured 43 alligators that had been tagged during the previous year (Table 1). Retention rates differed among tag types ($\chi^2 = 11.87$, df = 3, $P < 0.01$). Retention rates were greater for PIT tags than for foot and tail tags and the retention rate of T-bar anchor tags exceeded that for tail tags (Table 2). The foot webbing tags were the most cost effective, followed by the tail tags and T-bar anchor tags (Table 1). The most expensive method however, was PIT tagging (Table 1). Tail tags required the most assistance and effort followed by PIT tags and foot webbing tags (Table 1). The T-bar anchor tags required the least amount of assistance and effort (Table 1).

Of the 43 recaptured alligators, 40 had been tagged with PIT tags in 2012. A total of 39 (97%) of the 40 tagged alligators retained a working PIT tag implant upon recapture. The one failed PIT tag was from a male alligator that measured 69.3 cm TL. The time required to insert and scan the PIT tag and record the PIT tag number averaged 1.5 minutes. When inserting PIT tags, one person was needed for alligators ≤ 1 m TL, two people for alligators 1–1.5 m TL, and three for alligators > 1.5 m TL. The technology of the PIT tags was the most expensive of the four tags, costing $7.50/tag and the tag scanner cost $1685 (all prices quoted are as of 2013, in US dollars).

Forty of the 43 recaptured alligators (93%) retained the T-bar anchor tags from the previous year. The three tags that were lost were from females that ranged in size from 50 to 100 cm TL. Average time to successfully insert a T-bar anchor tag was < 10 seconds. Alligators < 2 m TL could be tagged by a single researcher, however individuals ≥ 2 m TL required additional restraint by field assistants. Day and nighttime visibility of T-bar anchor tags to the unaided eye of an experienced observer was determined to be ~37 and ~20 m, respectively. Floy T-bar anchor tags can be purchased in lots of 100 for $0.90/tag or in lots of 1000 for $0.67/tag. The tagging gun, which is required for the insertion of this tag, can be purchased for $55.00.

A total of 26 of the recaptured 43 alligators had been previously tagged with tail tags. Only 19 (73%) of the tagged alligators retained the tail tags. The seven failed tags were all from female alligators. Four missing tags were from alligators that were 50 to 100 cm TL, two from alligators 101 to 150 cm TL, and one from an individual that was 248 cm TL. The time required to insert a tail tag averaged 2 minutes. Individuals < 2 m TL required the assistance of one additional person while individuals ≥ 2 m TL

required the assistance of two additional field assistants. These tags are relatively inexpensive and can be purchased for $0.82/tag. The tail tags also require a tag applicator gun that can be purchased for $20.95.

Nineteen of the 43 recaptured alligators had been tagged with the Kemco foot webbing tags during the previous year and 15 (79%) retained the foot webbing tag after one year. Of the four lost tags, three were from females and one was from a male alligator. Two lost tags were from individuals that ranged in size from 150 to 200 cm TL and two were from individuals that measured ≥ 200 cm TL. On average the foot webbing tags could be inserted in 45 seconds. Alligators ≥ 2 m TL required assistance in tagging, while smaller alligators could be tagged easily by a single person. These tags were the least expensive of the four tags used in this study and can be purchased for $0.08/tag. Additionally, the tagging pliers, which are a necessity for this method, can be purchased for $20.00.

Discussion.—PIT tagging has been widely accepted as an efficient technique to uniquely mark and identify individuals across a wide array of taxa. PIT tags have been found to have high retention rates in a variety of species such as giant salamanders (*Cryptobranchus alleganiensis*; Unger et al. 2012), Muskellunge (*Esox masquinongy*; Jennings et al. 2009), and Rainbow Trout (*Oncorhynchus mykiss*; Meyer et al. 2011). We determined that T-bar anchor tags and PIT tags had high retention rates for the American Alligator. Although T-bar anchor tags have a high initial retention rate, retention rate decreased through time in the Gulf Sturgeon (*Acipenser oxyrinchus desotoi*) while PIT tag retention rates remained relatively constant (Buzby and Deegan 1999; Clugston 1996). The high rates of PIT tag and T-bar anchor tag retention are likely due to tag characteristics. The PIT tag is an internal tag that is not subjected to the exterior rigors of the daily environment of the American Alligator. Additionally, retention rate of T-bar anchor tags was greater than for tail tags, which could be the result of tag placement. Moreover, the T-bar anchor tags were placed at the base of the skull, which allows the tag to conform to the streamlined morphology of the individual and adhere to the contours of their movement throughout a rugged environment. The foot webbing tags are one of the most widely used tags in crocodilian research; however, retention was less than for other tag types. Tail tags were the least reliable tag, most likely due to tag size and insertion site. This is a likely explanation as to why the T-bar anchor tags had higher retention rates than other external tags. External tags are at a disadvantage for retention because of the likelihood of becoming entangled in surface and underwater debris present in alligator habitat. Entanglement may cause the tags to be avulsed from the insertion site, resulting in a failed tag and potentially causing injury to the animal. One case was noted in this study in which a recaptured individual was missing not only the tail tag, but also the tail scute that had served as the site of tag attachment (CBE, pers. obs.). The tail scute appeared to be avulsed from the alligator's body as the result of entanglement. Although the wound had healed and did not appear to inhibit the individual in any way, the injury may have caused unnecessary stress and damage to the alligator. The tail and feet are essential for locomotion both in the water and on land; the frequent movement of these anatomical components can cause increased stress and wear on tags, yielding missing, broken, or illegible tags, which can diminish or completely void the usefulness of the tags. Another probable cause of loss of foot webbing tags is growth of the individual. Although we were unable to determine it in this study, individuals may grow to a point at which the foot webbing tags become loose and fall out or are pushed out of the alligator's foot webbing. In addition, Bellini et al. (2001) found that corrosion was a factor in the loss of metal tags in sea turtles. Although a possibility, this was not likely a cause of tag loss in our study, as inspection of the retained tags did not indicate any signs of corrosion. Alligators tagged in this study inhabit freshwater wetlands and although freshwater also will corrode metal tags, they were not exposed to high salinity levels that are more conducive to the accelerated corrosion of metal.

When tagging larger alligators, it was necessary for field assistants to aid in the restraint of the animal while the PIT, tail, or foot webbing tags were inserted. By inserting tags into the tail or foot webbing, the person that is inserting the tag has very limited control of the animal's head. This introduces the risk of personal injury. By utilizing a tag insertion site closer to the head of the animal, as is done with the T-bar anchor tags, the person inserting the tag has more control of the alligator's head.This allows a single person to tag individuals that are much larger in size without the risk of personal bodily injury. Also, since T-bar anchor tags require less time for insertion, this method can reduce stress on captured alligators by reducing the amount of handling time, thereby allowing field crews more time to potentially tag more individuals. This method is unique in the fact that an alligator can be successfully tagged in a relatively short amount of time. The tag applicator can be loaded with multiple tags and does not require each tag to be loaded into the tag applicator individually. The rapid cartridge-fed applicator decreases the amount of time required to tag an individual and results in a quicker release. An alligator can be successfully tagged with this method in a matter of seconds by an experienced researcher. These other methods required more time to successfully tag an individual due to each tag having to be loaded into tag applicators and PIT tag syringes individually. Although the T-bar anchor and PIT tags could be used on all alligators regardless of size, this was not the case for tail and foot webbing tags.The diameter of the dermal hole (0.7 cm) created by tail tag insertion is too large to employ the tail tags for use on smaller alligators without causing unneeded harm to the individual. Due to the small amount of foot webbing on smaller alligators, the same can be said for the foot webbing tags.

A great disadvantage to the PIT, tail, and foot webbing tags is that in order to determine if an individual has been previously tagged, the individual must first be recaptured, restrained, and checked for a tag, which results in more effort for field crews and more stress on the captured animal. The visibility of these tags is minimal, or in the case of the PIT tags, completely nonexistent. Therefore, to identify an alligator that has been tagged with tail or foot webbing tags, researchers must spot them at an exceptionally close distance on land or in very shallow and clear

TABLE 2. Chi-square and P-values for pair-wise comparisons of alligator tag retention for four types of tags. Asterisks indicate significant differences.

	T-bar anchor		Foot		Tail	
	χ^2	P	χ^2	P	χ^2	P

Foot	–	–	–	–	0.41	>0.50
Tail	–	–	–	–	–	–

water. The T-bar anchor tag method is unique in the fact that these tags can be seen from a distance of ~37 m during the daytime and ~20 m during nighttime conditions, even if the majority of the individual's body is submerged beneath the water's surface. In mark-recapture studies, this allows researchers to determine from a distance if an individual was tagged without having to recapture the animal. This significantly reduces time required in handling animals and allows for more time searching for tagged individuals. This visibility allows observers to determine the proportion of the population that is tagged and has the potential to be used in mark-resight studies on crocodilian species. During nighttime searching, spotlighting causes the fluorescent tags to reflect light at a distance of up to ~20 m, yielding a visible tag even in low-light conditions.

Conclusions.—We suggest the use of the Floy T-bar anchor fish tags and PIT tags as a tagging strategy for the American Alligator primarily because the retention rate for each is >90% after one year. However, the T-bar anchor tags are also a good tagging strategy because they require less personnel to tag individuals; are a quicker method of tagging alligators; do not appear to harm alligators; do not cost substantially more than the cheaper methods, especially when accounting for cost of additional personnel for the other tagging methods; and do not require recapture of individuals to estimate marked populations. Due to the lower retention rates of the Kemco foot webbing tags and the tail tags, coupled with the physical stress for alligators and effort required of field crews, we do not suggest their use in studies on the American Alligator. Although the present study was conducted on American Alligators, the results of tag retention, as well as our novel tagging technique, should be applicable to the majority of crocodilians.

Acknowledgments.—We thank the Houston Livestock Show, the Henry L. Willet Foundation, the East Texas Herpetological Society, and the Brazos Bend State Park Volunteer Organization for funding provided for this study. This study would not have been possible without the field contributions of B. A. Eversole and J. L. Ogdee. We also thank the Texas Parks and Wildlife Department as well as staff and volunteers of Brazos Bend State Park for access to our study site and help with fieldwork. This is contribution number 13-125 of the Caesar Kleberg Wildlife Research Institute. This study was approved by the TAMUK Animal Care and Use Committee (Approval #1118).

Evaluation of Helminths Associated with 14 Amphibian Species from a Neotropical Island Near the Southeast Coast of Brazil

Brazil harbors a great diversity of amphibians, with approximately 877 species recorded (Segalla et al. 2012). The Atlantic Rain Forest (Mata Atlântica) biome significantly contributes to this high biodiversity, on the Brazilian coast and in fragments inside the country; more amphibian species live here than any other Brazilian biome, including many endemic species (IUCN 2006; SOS Mata Atlântica and INPE 2002). Some islands along the São Paulo State coast are priority areas for Atlantic Forest conservation, with unique biota for scientific investigations.

In island environments, information on helminth parasites associated with populations or communities remains scarce. Lent et al. (1946) researched helminth parasites of *Rhinella schneideri* (Werner, 1894) (syn. *Bufo paracnemis*) specimens from Isla Valle, Paraguay, and found two species of Digenea (*Catadiscus freitaslenti* Ruiz, 1943 and *Mesocoelium incognitum* Travassos, 1921) and one nematode species (*Ochoterenella digiticauda* Caballero, 1944), increasing the knowledge concerning the helminth fauna of anurans. Torres and Puga (1996) reported for the first time *Centrorhynchus* sp. (Acanthocephala) associated with *Eupsophus roseus* (Duméril and Bibron, 1841) from Isla Teja, and *Eupsophus calcaratus* (Günther, 1881) from Chiloé Island, Chile, increasing to ten the number of helminth species record in anurans of Chile. Ramalho et al. (2009), researching helminth parasites of lizards from the Fernando de Noronha Archipelago, Brazil, discovered three helminth species associated with an introduced lizard, *Salvator merianae* Duméril and Bibron, 1839 (syn. *Tupinambis merianae*), and seven helminth species associated with endemic lizards, *Trachylepis atlantica* (Schmidt, 1945) and *Amphisbaena ridley* Boulenger, 1890, suggesting that introduced lizards can carry other helminths to locations where they had not existed before, and that endemic lizards share parasite species with lizards that have been introduced.

Island research is interesting due to geographic isolation and the potential of endemic species (MacArthur and Wilson 1967; Vitousek et al. 1995). However, it is questionable whether Anchieta Island, an island near the north coast of São Paulo, Brazil, is in fact isolated, due to its distance of only 8 km from the continent and receiving visitors of 80,000 people annually to Anchieta Island State Park (www.iflorestal.sp.gov.br). The environment of this island, as well as fragments of Mata Atlântica, has been altered by human development. Unfortunately, there is little information about the endemic fauna of this area. In a herpetofaunal survey of Anchieta Island, Cicchi et al. (2009) reported the following anurans: *Fritziana fissilis* (Miranda-Ribeiro, 1920) (syn. *Flectonotus fissilis*) (Hemiphractidae); *Haddadus binotatus* (Spix, 1824) (Craugastoridae); *Ischnocnema bolbodactyla* (Lutz, 1925); *Ischnocnema parva* (Girard, 1853) (Brachycephalidae); *Rhinella ornata* (Spix, 1824); *Dendrophryniscus brevipollicatus* Jiménez de la Espada, 1870 (Bufonidae); *Hypsiboas albomarginatus* (Spix, 1824); *Scinax hayii* (Barbour, 1909) (Hylidae); *Hylodes asper* (Müller, 1924); *Hylodes phyllodes* Heyer and Cocroft, 1986 (Hylodidae); *Leptodactylus* cf. *marmoratus* (Steindachner, 1867); *Leptodactylus latrans* (Steffen, 1815) (Leptodactylidae); *Chiasmocleis carvalhoi* Cruz, Caramaschi, and Izecksohn, 1997; and *Myersiella microps* (Duméril and Bibron, 1841) (Microhylidae). It is likely that many other anurans are not yet discovered.

The helminth fauna associated with amphibians comprises general parasites (Aho 1990) with a low specificity with their hosts. Therefore, there are frequently new records of hosts harboring parasites that have not previously been related to them. Herein, this study reports the helminth fauna associated to 14 amphibian species, of the Mata Atlântica biome occurring in Anchieta Island Park State an insular environment, of a biome with high endemism and biodiversity in which very little is known. Moreover, we also summarize the known distributions of these helminth parasites in South America to present the state of knowledge about biodiversity of helminthes associated to amphibians from South America. This source will be important for futures studies on this subject.

Anurans were collected from the preserved area of Mata Atlântica, Anchieta Island State Park (23.45°S, 45.033°W), Ubatuba municipality. The island consists of 828 ha of Dense Rain Forest and Restinga forests (Veloso et al. 1991). Its regional climate is typically tropical humid, with no dry season (Nimer 1989). Anurans were collected monthly from July 2005 to June 2006, using pitfall traps, a visual encounter survey, and opportunistic collection. The specimens were identified, fixed (10% formaldehyde), maintained in alcohol and deposited in the Coleção de Vertebrados Dr. Jorge Jim (CVJJ) of the Universidade Estadual Paulista (UNESP/Botucatu). For parasitological studies, 194 anurans of 14 species were necropsied: *F. fissilis* (N = 18); *H. binotatus* (N = 9); *I. bolbodactyla* (N = 4); *I. parva* (N = 20); *R. ornata* (N = 20); *D. brevipollicatus* (N = 3); *H. albomarginatus* (N = 18); *S. hayii* (N = 23); *H. asper* (N = 2); *H. phyllodes* (N = 3); *L.* cf. *marmoratus* (N = 40); *L. latrans* (N = 5); *C. carvalhoi* (N = 26); and *M. microps* (N = 3).

During necropsy, hosts were sexed and the body cavity, digestive tract, accessory organs and musculature were examined for helminth parasites. The helminth parasites were counted and preserved in 70% ethyl alcohol. For identification, the helminths were examined as temporary mounts: nematodes were cleared with lactophenol, whereas acanthocephalans and cestodes were stained with carmine and cleared with eugenol or creosote. The helminths were analyzed using a computerized image analysis system (Qwin Lite 3.1; Leica Microsystems, Wetzlar, Germany).

The systematic determination of the helminths was conducted following the methods of Yamaguti (1959, 1961, 1963), Vicente et al. (1991), Anderson et al. (2009), and Gibbons (2010). The infection prevalence, mean abundance (MA) and mean intensity of infection (MII) were calculated for helminths according to Bush et al. (1997). MII and MA are presented as mean values with their standard errors.

A total of 2058 helminths were collected from 103 of 195 anuran specimens examined, representing an overall prevalence of 52.82% (Table 1) and an MA of 10.55 ± 4.87. The parasitized individuals were infected with an average of 19.98 ± 9.24 helminth indivuduals per host. In the anuran community, we identified a species of Cestoda, *Cylindrotaenia* cf. *americana* Jewell, 1916 (N = 7), a species of Acanthocephala (N = 54) and 12 species of Nematoda including: *Falcaustra mascula* (Rudolphi, 1819) (N = 2); *Oxyascaris oxyascaris* Travassos, 1920 (N= 9); *Oswaldocruzia* sp. (N = 6); *Rhabdias* sp. (N = 31); and *Physaloptera* sp. (N = 86), and a total of 1078 cosmocercids. Of the cosmocercids samples that were male, it was possible to identify the following species: *Aplectana pintoi* Travassos, 1925 (N = 5); *Aplectana crucifer* Travassos, 1925 (N = 3); *Aplectana* sp. (N = 13); *Cosmocerca brasiliense* Travassos, 1925 (N = 11); *Cosmocerca parva* Travassos, 1925 (N = 1); *Cosmocerca travassosi* Rodrigues and Fabio, 1970 (N = 11); and *Cosmocerca* sp. (N = 14). Unidentified nematode larvae (N = 784) parasitized nine of the 14 anuran species examined. Each parasitized individual was infected with an average of 1.56 ± 0.08 helminth species.

Overall, cosmocercids were the most common helminth, with a prevalence of 35.38% and an MA of 5.53 ± 10.37. The next most-common helminth was *Physaloptera* sp., with a prevalence of 11% and an MA of 0.4 ± 0.18. The other helminth species had low prevalence, MA and MII (see Appendix).

Among the analyzed hosts, the *L. latrans* specimens were highly parasitized (100%), followed by *H. binotatus* (88.9%) and

TABLE 2. Overall Prevalence (P%), number of recovered helminths (RH), mean abundance (MA), mean intensity of infection (MII) followed by standard error (SE), of helminths associated to 14 anuran species from Anchieta Island, São Paulo State, Brazil.

Hosts	P(%)	RH	MA ± SE	MII ± SE

TABLE 3. Countries and localities reported for helminths associated with anurans from South America. Abbreviation of Brazilian States is informed within brackets.

Countries	Localities (states, cities or provinces)
Brazil	Amazonas (AM), Bahia (BA), Distrito Federal (DF), Espírito Santo (ES), Goias (GO), Mato Grosso do Sul (MS), Para (PA), Paraná (PR), Rio de Janeiro (RJ), Rio Grande do Sul (RS), Santa Catarina (SC), São Paulo (SP), and Tocantins (TO)
Argentina	Corrientes
Chile	Locality not reported
Colombia	Central Cordillera
Ecuador	Pastaza and Santa Cecilia
French Guiana	Comté
Guyana	Rupunini
Paraguay	Assuncion, Chaco-I, and Remanso Castillo
Peru	Cuzco, Lima, Piura, and Ucayali

R. ornata (75%). *Haddadus binotatus* had a high MA of helminths (78.3 ± 70.7) as well as MII (88.1 ± 79.4). *Scinax hayii* had a high MII due to many nematode larvae parasitizing one individual host (MII = 235 ± 233.5). On the other hand, *I. bolbodactyla* specimens had both a low MA (0.25 ± 0.25) and MII (1.0) (Table 2).

In an Appendix, we list the helminth species of this study with the percentage prevalence and MII per host species, together with the status distribution of these helminths in South American hosts. The localities, as cities or states, are indicated within parentheses followed by the reported host. In all, 27 localities were reported in nine countries from South America (Table 3). The bibliography of helminth species reported for anurans from South American continent were based on information from both online databases (such as BioOne, Isi, Jstor, PubMed, Scielo, Scopus, and Web of Science) and published monographs (Yamaguti 1959, 1961, 1963).

We present the first report of helminth fauna from nine anuran species (*F. fissilis*, *I. bolbodactyla*, *R. ornata*, *D. brevipollicatus*, *H. albomarginatus*, *S. hayii*, *H. asper*, *C. carvalhoi*, and *M. microps*). Only five host species (*H. binotatus*, *I. parva*, *H. phyllodes*, *L.* cf. *marmoratus*, and *L. latrans*) have been reported on the continent; however, this study is the only one that has been performed in South America regarding helminths associated with anurans from an insular environment. All helminths found here were previously reported in anurans from the South American continent; however, there were 12 helminth species recorded in new hosts. Only *Oxyascaris oxyascaris* and *Falcaustra mascula* have been reported parasitizing *Leptodactylus latrans* (Stumpf 1982; Baker and Vaucher 1985; Rodrigues et al. 1990; Vicente et al. 1991). Anchieta Island is currently a conservation area, where the parasitic fauna of anurans has never been studied; for some helminthes, we present the parasitism in anurans species for the first time: 1) *Haddadus binotatus* is a new record for *Oswaldocruzia* sp., *Rhabdias* sp., *Physaloptera* sp., *A. pintoi* and *C. brasiliense*; 2) *H. phyllodes* is a new record for *Rhabdias* sp., *C. brasiliense* and *C.* cf. *Americana*; 3) *L.* cf. *marmoratus* is a new record for *Rhabdias* sp.

Of all the helminths reported in this study, acanthocephalans were the least frequent (Smales 2007). This is due to the transmission of acanthocephalans to anurans occurring by ingestion of invertebrates parasitized with cystacants that infect the gastrointestinal tract (Kennedy 2006), making the anuran a definitive or paratenic host (Smales 2007; Pinhão et al. 2009; Santos and Amato 2010b). The cestode *Cylindrotaenia* cf. *americana* is a Western-hemisphere species known to infect anurans of the families Bufonidae, Ranidae, Hylidae, Leptodactylidae, and Dendrobatidae (Jones 1987; Bursey et al. 2001). The parasitism of this cestode in *H. phyllodes* and *I. parva* adds two anuran families, Hylodidae and Brachycephalidae, to this list. The nematodes of Cosmocercidae family are transmitted directly; the final host is infected by ingestion of eggs containing infective larvae (*Aplectana* spp.) or by infective larvae that penetrate actively in the host's tegument (*Cosmocerca* spp.) (Anderson

2000). These parasites were highly prevalent, and had high MA and MII, corroborating the general pattern of these helminths of amphibians (Aho 1990; Bursey et al. 2001). This is due to the fact that these helminths have to infect their hosts directly, without intermediate hosts to complete their biological cycle (Anderson 2000; Hamann et al. 2006b). The infection by *Rhabdias* spp. and *Oswaldocruzia* spp. occurs similarly, transmitted directly by larvae that penetrate actively in the host's tegument. *Rhabdias* spp. infection occurs only by parthenogenetic females that alternate between free-living and parasitic existence on amphibian lungs (Anderson 2000). About the Kathlaniidae (*F. mascula* and *O. oxyascaris*), a nematode family, very little is known concerning their indirect transmission; Anderson (2000) suggests that possibly kathlaniids in the lower vertebrates develop to the third stage outside the host and then invade various invertebrates which serve as paratenic hosts.

Physaloptera spp. parasitize mammals and reptiles, and do not complete their life cycle in amphibians. Larvae of *Physaloptera* sp. are found in the stomach mucosa of amphibians that ingest larvae-infected insects, so the amphibian can be an intermediate or paratenic host (Anderson 2000). We did not find these larvae in five host species: *D. brevipollicatus* (N = 3), *I. bolbodactyla* (N = 4), *I. parva* (N = 20), *H. asper* (N = 2), and *M. microps* (N = 3). Excepting for *I. parva*, this can due to the fact that there were low sample sizes of these anurans. Also, the absence of infection with *Physaloptera* sp. in these anurans can be explained by their feeding, which may not transmit *Physaloptera* spp. larvae. The anurans have a generalized diet, eating any arthropods, but some, as those cited above, frequently feed ants and isopods (AmphibiaWeb 2014). Studies concerning the life cycle of *Physaloptera* spp. indicate the more commum intermediate hosts are cockroaches (*Blatella germanica*) (Alicata 1937; Hobmaier 1941; Lee 1955). Thus, we may consider that the absence of *Physaloptera* sp. is related to diet of anurans.

We found at least 14 helminth species associated with anurans from Anchieta Island; of these, four species have an indirect life cycle, where an intermediate host is required for completion of the parasite's cycle. The other 10 species are transmitted directly, and do not require an intermediate host. So, in this way, they have success in their life cycle. Digenean trematodes, with two or more intermediate hosts, were not found in anurans from Anchieta Island, possibly due to the absence of the intermediate hosts required for the biological cycle of these helminths. Even though trematodes have been found frequently on the continent in Brazilian anurans (Travassos et. al. 1969), it is likely that parasites with heteroxenic cycles have difficulty establishing themselves in insular environments. On the other hand, the composition of anuran helminth fauna of Anchieta Island is similar to the mainland, all helminth species are commonly associated to anurans from continent.

Anchieta Island has a continental origin, occurring on the Brazilian continental shelf, and it exists now as an island due to one or more of the several oscillations of sea level during the Pleistocene (Martin et al. 1986), the last of which occurred about 11,000 yrs ago (Souza et al. 2005). The common geological origin and the short distance to the mainland (8 km) have consequences such as the island and mainland having the same vegetation (Atlantic Rain Forest - "Mata Atlântica") and climatic conditions which are similar to littoral coast, allowing the development of the same species. It is expected that continental islands present a similar fauna to the continent, since this isolated portion of land has been directly connected to the continent. Thus, there is still a need for zoological studies in insular environments, allowing observations of the similarity to the continent or to neighboring islands, as well as detection of possible introduced species or local extinctions.

The knowledge of parasite communities in amphibian hosts and the patterns and processes underlying their structure has grown, but most of the studies have been performed with species from temperate latitudes (Aho 1990). Our study addresses helminths associated with 14 anuran species from Mata Atlântica reports nine new records species, is the first report of helminth fauna associated to insular anurans, and represents a contribution to the knowledge of amphibian helminth fauna from the Neotropical region.

APPENDIX I

Nematoda
Rhabdiasidae
***Rhabdias* sp.**

Host, P% and IMI: *R. ornata* (P= 40%; IMI=2.1 ± 0.4), *H. binotatus* (P = 22.2%; IMI = 2.5 ± 1.5), *S. hayii* (P = 4.3%; IMI = 2.0), *H. albomarginatus* (P = 11.1%; IMI = 2.0 ± 1.0), *L. cf. marmoratus* (P = 2.4%; IMI= 2.0) and *C. carvalhoi* (P = 3.8%; IMI = 1.0).

Site of infection: lungs.

Other reported hosts and locality: *Hypsiboas albopunctatus* (Spix, 1824) (GO, DF), *Leptodactylus chaquensis* Cei, 1950 (Corrientes), *L. latrans* (syn. *Leptodactylus ocellatus*) (PA, RJ), *Leptodactylus podicipinus* (Cope, 1862) (MS), *Pseudis platensis* Gallardo, 1961 (MS), *Rhinella bergi* (Céspedez, 2000) (Corrientes), *Rhinella crucifer* (Wied-Neuwied, 1821) (syn. *Bufo crucifer*) (RJ), *Rhinella icterica* (Spix, 1824) (syn. *Bufo ictericus*) (ES) and *Rhinella marina* (Linnaeus, 1758) (syn. *Bufo marinus*) (PA).

Geographic range: Argentina (González and Hamann 2007b; Hamann et al. 2006b) and Brazil (Campião et al. 2009, 2010; Fabio 1982; Holmes et al. 2008; Rodrigues 1986; Rodrigues et al. 1982, 1990; Travassos et al. 1939; Travassos and Freitas 1964; Vicente et al. 1991; Vicente and Santos 1976).

Remarks: *R. ornata, H. binotatus, S. hayii, H. albomarginatus, L.* cf. *marmoratus* and *C. carvalhoi* represent new host records for the genus *Rhabdias*; Anchieta Island is a new locality record.

Molineidae
***Oswaldocruzia* sp.**

Host, P% and IMI: *R. ornata* (P = 10%; IMI = 2.0 ± 0) and *H. binotatus* (P = 22.2%; IMI = 1.0 ± 0).

Site of infection: small intestine.

Other reported hosts and locality: *Hypsiboas boans* (Linnaeus, 1758) (syn. *Hyla boans*) (AM), *Hypsiboas* sp. (MS), *Leptodactylus bufonius* Boulenger, 1894 (Corrientes), *Leptodactylus fuscus* (Schneider, 1799) (syn. *Leptodactylus sibilatrix*) (ES), *L. latrans* (syn. *L. ocellatus*) (PA), *Leptodactylus pentadactylus* (Laurenti, 1768) (Comté), *Lysapsus limellum* Cope, 1862 (syn. *Pseudis limellum*) (PA), *Physalaemus albonotatus* (Steindachner, 1864) (Corrientes), *Rhinella crucifer* (syn. *B. crucifer*) (RJ), *Rhinella fernandezae* (Gallardo, 1957) (RS), *R. icterica* (syn. *Bufo ictericus* and *Chaunus ictericus*) (ES, RJ, SC), *Rhinella granulosa* (Spix, 1824) (syn. *Bufo granulosus*) (PA), *R. marina* (syn. *Bufo marinus*) (AM, PA) and *Rhinella schneideri* (syn. *Chaunus schneideri*) (MS).

Geographic range: Argentina (González and Hamann 2006b, 2012), Brazil (Gonçalves et al. 2002; Luque et al. 2005; Lux Hoppe et al. 2008; Rodrigues et al. 1982; Rodrigues 1986; Santos and Amato 2010a; Travassos et al. 1939, 1964; Travassos and Freitas 1941, 1964; Vicente et al. 1991) and French Guiana (Ben Slimane and Durette-Desset 1996).

Remarks: *R. ornata* and *H. binotatus* represent new host records for *Oswaldocruzia* sp.; as species determination was based on male characteristics, it was not possible to assign a species designation for our nematode. Anchieta Island is a new locality record.

Physalopteridae
***Physaloptera* sp.**

Host, P% and IMI: *R. ornata* (P = 20%; IMI = 2.7 ± 1.2), *H. binotatus* (P = 33.3%; IMI = 12.0 ± 8.5), *F. fissilis* (P = 16.7%; IMI = 1.7 ± 0.7), *S. hayii* (P = 8.7%; IMI = 1.0), *H. albomarginatus* (P = 22.2%; IMI = 5.7 ± 4.4), *H. phyllodes* (P = 33.3 %; IMI = 1.0), *L. latrans* (P = 25%; IMI = 5.0), *L. cf. marmoratus* (P = 2.4%; IMI = 1.0), *C. carvalhoi* (P = 7.7%; IMI = 1.0 ± 0) and *M. microps* (P = 10%; IMI = 2.0 ± 0).

Site of infection: stomach.

Other reported hosts and locality: *Allobates marchesianus* (Melin, 1941) (syn. *Colostethus marchesianus*) (Cuzco), *Ctenophryne geayi* Mocquard, 1904 (Cuzco), *Dendropsophus leali* (Bokermann, 1964) (syn. *Hyla leali*) (Cuzco), *Dendropsophus leucophyllatus* (Beireis, 1783) (syn. *Hyla leucophyllatus*) (Cuzco), *Dendropsophus marmoratus* (Laurenti, 1768) (syn. *Hyla marmorata*) (Cuzco), *Edalorhina perezi* Jiménez de la Espada, 1870 (Cuzco), *Hamptophryne boliviana* (Parker, 1927) (Cuzco), *Hypsiboas boans* (syn. *Hyla boans*) (Cuzco), *Hypsiboas faber* (Wied-Neuwied, 1821) (syn. *Hyla faber*) (RJ), *Hypsiboas cinerascens* (Spix, 1824) (syn. *Hyla granosa*) (Cuzco), *Hypsiboas fasciatus* (Günther, 1858) (syn. *Hyla fasciata*) (Cuzco), *Leptodactylus bolivianus* Boulenger, 1898 (Cuzco), *L. bufonius* (Corrientes), *L. latrans* (syn. *Leptodactylus caliginosis* and *L. ocellatus*) (RJ, TO), *Leptodactylus leptodactyloides* (Andersson, 1945) (TO, Cuzco), *Leptodactylus lineatus* (Schneider, 1799) (syn. *Lithodytes lineatus*) (Cuzco), *L. marmoratus* (syn. *Adenomera marmorata*) (RJ), *Leptodactylus mystaceus* (Spix, 1824) (RJ, Cuzco), *L. pentadactylus* (Cuzco), *Leptodactylus petersii* (Steindachner, 1864) (TO), *Leptodactylus rhodonotus* (Günther, 1869) (Cuzco), *Osteocephalus taurinus* Steindachner, 1862 (Cuzco), *Oreobates cruralis* (Boulenger, 1902) (syn. *Eleutherodactylus curalis*) (Cuzco), *Phyllomedusa tomopterna* (Cope, 1868) (Cuzco), *P. albonotatus* (Corrientes), *Physalaemus santafecinus* Barrio, 1965 (Corrientes), *Physalaemus signifer* (Girard, 1853) (RJ), *Physalaemus soaresi* Izecksohn, 1965 (RJ), *Pristimantis fenestratus* (Steindachner, 1864) (syn. *Eleutherodactylus fenestratus*) (Cuzco), *Proceratophrys appendiculata* (Günther, 1873) (RJ), *Proceratophrys boiei* (Wied-Neuwied, 1824) (RJ), *Pseudis paradoxa* (Linnaeus, 1758) (Cuzco), *R. fernandezae* (Corrientes), *R. granulosa* (Corrientes), *R. icterica* (SP), *Rhinella margaritifera* (Laurenti, 1768) (syn. *Bufo typhonius*) (Cuzco), *R. marina* (syn. *B. marinus*) (AM, PA, Cuzco), *R. schneideri* (Corrientes), *Scinax acuminatus* (Cope, 1862) (Corrientes), *Scinax ictericus* Duellman and Wiens, 1993 (Cuzco), *Scinax nasicus* (Cope, 1862) (Corrientes), *Scinax ruber* (Laurenti, 1768) (Cuzco), *Trachycephalus coriaceus* (Peters, 1867) (syn. *Phrynoyas coriacea*) (Cuzco) and *Trachycephalus typhonius* (Linnaeus, 1758) (syn. *Phrynohyas venulosa*) (Cuzco).

Geographic range: Argentina (González and Hamann 2006a, 2006b, 2007a, 2008, 2010, 2012; Hamann et al. 2010), Brazil (Boquimpani-Freitas et al. 2001; Fabio 1982; Goldberg et al. 2009; Gonçalves et al. 2002; Klaion et al. 2011; Pinhão et al. 2009; Travassos 1925; Travassos and Freitas 1964; Vicente et al. 1991) and Peru (Bursey et al. 2001).

Remarks: *R. ornata, H. binotatus, F. fissilis, S. hayii, H. albomarginatus, H. phyllodes, C. carvalhoi* and *M. microps* represent new host records for larvae of *Physaloptera* sp., but larval characteristics did not allow a species designation for our nematode. Anchieta Island is a new locality record.

Kathlaniidae
Falcaustra mascula

Host, P% and IMI: *L. latrans* (P = 25%; IMI = 2.0)

Site of infection: large intestine

Other reported hosts and locality: *Crossodactylus gaudichaudii* Duméril and Bibron, 1841 (RJ), *Hylodes nasus* (Lichtenstein, 1823) (Brazil), *Hypsiboas albopunctatus* (DF), *H. faber* (syn. *H. faber*) (Brazil), *Ischnocnema guentheri* (Steindachner, 1864) (syn. *Eleutherodactylus guentheri*) (RJ), *I. parva* (syn. *Eleutherodactylus parvus*) (RJ), *Leptodactylus vastus* A. Lutz, 1930 (syn. *Leptodactylus labyrinthicus*) (BA), *Leptodactylus labyrinthicus* (Spix, 1824) (BA, RJ), *L. latrans* (syn. *L. ocellatus)* (PR, RJ, Assuncion, Chaco-I, Remanso Castillo), *Leptodactylus rhodomystax* Boulenger, 1884 (PA), *Rhinella granulosa* (syn. *B. marinus*) (RJ), *Rhinella icterica* (syn. *Bufo marinus ictericus* and *Bufo ictericus*) (RJ) and *R. schneideri* (Corrientes, Assuncion, Chaco-I, Remanso Castillo).
Geographic range: Argentina (González and Hamann 2008), Brazil (Fabio 1982; Fahel 1952; Freitas and Lent 1941; Goldberg et al. 2007; Holmes et al. 2008; Luque et al. 2005; Martins and Fabio 2005; Rodrigues et al. 1982; Stumpf 1982; Travassos 1925; Vicente and Santos 1976; Vicente et al. 1991,) and Paraguay (Lent et al. 1946, McAllister et al. 2010b).
Remarks: Three species of *Falcaustra* have been reported from South America. Anchieta Island is a new locality record for *F. mascula*.

Oxyascaris oxyascaris
Host, P% and IMI: *L. latrans* (P = 50%; IMI = 4.5 ± 0.5).
Site of infection: large and small intestines.
Other reported hosts and locality: *I. guentheri* (syn. *E. guentheri*) (RJ), *Leptodactylus fuscus* (MS), *Leptodactylus macrosternum* Miranda-Ribeiro, 1926 (Paraguay), *L. mystaceus* (RJ), *Leptodactylus mystacinus* (Burmeister, 1861) (MS), *L. latrans* (syn. *L. ocellatus*) (PR, SP), *Physalaemus signifer* (RJ), *P. soaresi* (RJ), *Pleurodema diplolister* (Peters, 1870) (BA), *Proceratophrys boiei* (RJ) and *Rhinella schneideri* (Paraguay).
Geographic range: Brazil (Fabio 1980, 1982; Klaion et al. 2011; Martins and Fabio 2005; Rodrigues 1986; Rodrigues et al. 1990; Travassos 1920, 1925; Vicente and Santos 1976; Vicente et al. 1991) and Paraguay (Baker and Vaucher 1985).
Remarks: Anchieta Island is a new locality record for *O. oxyascaris*.

Cosmocercidae
Cosmocercidae gen. sp.
Host, P% and IMI: *S. hayii* (P = 4.3%; IMI = 1.0), *C. carvalhoi* (P = 88.5%; IMI = 7.5 ± 1.6), *H. asper* (P = 50%; IMI = 17.0), *H. phyllodes* (P = 66.7%; IMI = 3.5 ± 0.5), *L. cf. marmoratus* (P = 9.5%; IMI = 5.0 ± 2.2), *L. latrans* (P = 50%; IMI = 10.0 ± 9.0), *R. ornata* (P = 65%; IMI = 11.6 ± 5.2), *D. brevipollicatus* (P = 66.7%; IMI = 3.0 ± 1.0), *I. parva* (P = 70%; IMI = 1.7 ± 0.2) and *H. binotatus* (P = 77.8%; 94.1 ± IMI = 89.9).
Site of infection: stomach, large and small intestines.
Other reported hosts and locality: *Dermatonotus muelleri* (Boettger, 1885) (MS), *Eupemphix nattereri* Steindachner, 1863 (MS), *Hypsiboas prasinus* (Burmeister, 1856) (SP), *Leptodactylus latrans* (syn. *Leptodactylus ocellatus*) (MS, RJ), *L. pentadactylus* (RJ), *L. podicipinus* (MS), *Phyllomedusa azurea* Cope, 1862 (MS), *Rhinella crucifer* (syn. *Bufo crucifer*) (RJ), *R. granulosa* (MS) *R. icterica* (SP and RJ), *R. marina* (MS), *R. schneideri* (syn. *Bufo marinus*) (MS) and *Stereocyclops incrassatus* Cope, 1870 (syn. *Hypopachus incrassatus*) (MS).
Geographic range: Brazil (Campião et al. 2012, 2014; Chabaud 1978; Madelaire et al. 2012; Pinhão et al. 2009; Rodrigues et al. 1982, 1990; Travassos and Freitas 1942; Vicente et al. 1991).
Remarks: This nematode is a very common parasite of amphibians, but *S. hayii, C. carvalhoi, H. asper, H. phyllodes, R. ornata* and *D. brevipollicatus* represent new host records for cosmocercids, and this study is the first report regarding helminth fauna of these anurans; only *H. phyllodes* has an acanthocephalan species reported: *Anuracanthorhyncus tritaxisentis* Bursey, Vrcibradic, Hatano and Rocha 2006. Specimens reported here as Cosmocercidae gen. sp., as well as prevalence and MII correspond to females and males of this helminth family. Congeneric females are very similar and specific identification was not possible based on morphological characteristics. Only males were identified based on morphology and size of taxonomic characteristics; these species identified are listed as follows. This segregated view between males and females for the present study is due to uncertainty of whether females belong to the same species as males, as well as the scarce research descriptions of female specimens.

Aplectana crucifer
Host: *R. ornata*
Site of infection: large intestine
Other reported hosts and locality: *R. crucifer* (syn. *Bufo crucifer*) (RJ).
Geographic range: Brazil (Travassos 1925, 1931; Vicente et al. 1991) and Paraguay (McAllister et al. 2010b).
Remarks: *R. ornata* represents the second host record for *Aplectana crucifer* in South America, and this study is the first report concerning helminth fauna of this anuran.

Aplectana pintoi
Host: *I. parva* and *H. binotatus*
Site of infection: small and large intestines.
Other reported hosts and locality: *Craugastor gollmeri* (Peters, 1863) (syn. *Eleutherodactylus gollmeri*) (RJ) and *Ischnocnema guentheri* (syn. *Hylodes guentheri*) (RJ).
Geographic range: Brazil (Travassos 1925, 1931; Vicente et al. 1991).
Remarks: *I. parva* and *H. binotatus* represent the third and fourth host records for *Aplectana pintoi* in South America. Anchieta Island is a new locality record for *A. pintoi*.

***Aplectana* sp.**
Host: *C. carvalhoi*
Site of infection: large intestine
Other reported hosts and locality: *Ceratophrys cranwelli* Barrio, 1980 (MS), *Dendropsophus microps* (Peters, 1872) (syn. *Hyla microps*) (Brazil), *Dermatonotus muelleri* (MS), *Haddadus binotatus* (syn. *Hylodes binotatus*) (Brazil), *Hypsiboas albopunctatus* (DF), *Hypsiboas pardalis* (Spix, 1824) (syn. *Hyla pardalis*) (Brazil), *Leptodactylus bufonius* (Corrientes), *L. chaquensis* (Corrientes), *Leptodactylus elenae* Heyer, 1978 (MS), *L. fuscus* (MS), *L. marmoratus* (syn. *Adenomera marmorata*) (RJ), *L. mystacinus* (MS), *L. podicipinus* (MS), *Leptodactylus syphax* Bokermann, 1969 (MS), *Physalaemus signifier* (RJ), *Rhinella granulosa* (syn. *Bufo granulosus*) (PA), *R. icterica* (syn. *Bufo ictericus*) (ES, RJ), and *R. marina* (syn. *Bufo marinus*) (PA), *Scinax acuminatus* (syn. *Hyla phrynoderma*) (MS), *Thoropa miliaris* (Spix, 1824) (Brazil) and *Trachycephalus mesophaeus* (Hensel, 1867) (syn. *Hyla mesophaea*) (Brazil).
Geographic range: Argentina (González and Hamann 2006b, Schaefer et al. 2006), Brazil (Chabaud 1978; Fabio 1982; Holmes et al. 2008; Luque et al. 2005; Rodrigues et al. 1990; Travassos 1925; Travassos et al. 1939, 1964; Travassos and Freitas 1964; Vicente and Pinto 1981; Vicente et al. 1991;) and Paraguay (Baker and Vaucher 1986).
Remarks: *C. carvalhoi* represents a new host record for *Aplectana* sp., and this study is the first report concerning helminth fauna of this anuran. There are 23 Neotropical species of *Aplectana*, but characteristics did not allow a species designation for our nematode. Anchieta Island is a new locality record for *Aplectana* sp.

Cosmocerca brasiliense
Host: *R. ornata, H. binotatus* and *H. phyllodes*.
Site of infection: small and large intestines.
Other reported hosts and locality: *Ameerega parvula* (Boulenger, 1882) (syn. *Dendrobates parvulus*) (Santa Cecilia), *Dendropsophus brevifrons* (Duellman and Crump, 1974) (syn. *Hyla brevifrons*) (Cuzco), *Dendropsophus cachimbo* (Napoli and Caramaschi, 1999) (PA), *Dendropsophus koechlini* (Duellman and Trueb, 1989) (syn. *Hyla koechlini*) (Cuzco), *D. leali* (syn. *Hyla leali*) (Cuzco), *D. leucophyllatus* (syn. *Hyla leucophyllata*) (Cuzco),

D. marmoratus (syn. *Hyla marmorata*) (Pastaza), *Dendropsophus parviceps* (Boulenger, 1882) (syn. *Hyla parviceps*) (Cuzco), *Dendropsophus rhodopeplus* (Günther, 1858) (syn. *Hyla rhodopepla*) (Cuzco), *Dendropsophus sarayacuensis* (Shreve, 1935) (Santa Cecilia), *Dendropsophus schubarti* (Bokermann, 1963) (syn. *Hyla schubarti*) (Cuzco), *Edalorhina perezi* (Cuzco), *Eleutherodactylus* sp. (Santa Cecilia), *Hamptophryne boliviana* (Cuzco), *Hypsiboas boans* (syn. *Hyla boans*) (Cuzco), *Hypsiboas calcaratus* (Troschel, 1848) (syn. *Hyla calcarata*) (Cuzco), *H. cinerascens* (syn. *Hyla granosa*) (Cuzco), *H. fasciatus* (syn. *Hyla fasciata*) (Cuzco), *Hypsiboas geographicus* (Spix, 1824) (Santa Cecilia), *Hypsiboas lanciformis* Cope, 1871 (Santa Cecilia and Pastaza), *H. faber* (syn. *Hyla faber*) (RJ), *Hypsiboas punctatus* (Schneider, 1799) (Pastaza), *Ischnocnema guentheri* (syn. *Hylodes guentheri* and *Eleutherodactylus guentheri*) (RJ), *Leptodactylus andreae* Müller, 1923 (syn. *Adenomera andreae*) (Cuzco), *L. bolivianus* (Cuzco), *Leptodactylus hylaedactylus* (Cope, 1868) (syn. *Adenomera hyeleadactyla*) (Cuzco), *L. latrans* (syn. *Leptodactylus ocellatus*) (Rupunini), *L. pentadactylus* (Cuzco), *L. petersii* (Cuzco), *L. podicipinus* (Rupunini), *Oreobates cruralis* (syn. *Eleutherodactylus cruralis*) (Cuzco), *Oreobates quixensis* Jiménez de la Espada, 1872 (Cuzco), *Osteocephalus taurinus* (Cuzco), *Phyllomedusa atelopoides* Duellman, Cadle, and Cannatella, 1988 (Cuzco), *Phyllomedusa palliata* Peters, 1873 (Cuzco), *Phyllomedusa tarsius* (Cope, 1868) (Cuzco), *P. tomopterna* (Cuzco), *Phyllomedusa vaillanti* Boulenger, 1882 (Cuzco), *Pristimantis altamazonicus* (Barbour and Dunn, 1921) (syn. *Eleutherodactylus altamazonicus*) (Santa Cecilia), *P. fenestratus* (syn. *Eleutherodactylus fenestratus*) (Cuzco), *Pristimantis lanthanites* (Lynch, 1975) (syn. *Eleutherodactylus lanthanites*) (Cuzco), *Pristimantis peruvianus* (Melin, 1941) (syn. *Eleutherodactylus peruvianus*) (Cuzco), *Pristimantis toftae* (Duellman, 1978) (syn. *Eleutherodactylus toftae*) (Cuzco), *Proceratophrys appendiculata* (RJ), *Rhinella crucifer* (syn. *Bufo crucifer*) (RJ), *R. marina* (syn. *Bufo marinus*) (Cuzco), *Scarthyla goinorum* (Bokermann, 1962) (syn. *Scarthyla ostinodactyla*) (Cuzco), *Scinax garbei* (Miranda-Ribeiro, 1926) (Cuzco), *S. ictericus* (Cuzco), *Scinax pedromedinae* (Henle, 1991) (Cuzco), *S. ruber* (Pastaza), *Sphaenorhynchus lacteus* (Daudin, 1800) (Cuzco), *Thoropa miliaris* (RJ) and *Trachycephalus coriaceus* (syn. *Phrynohyas coriacea*) (Cuzco).

Geographic range: Brazil (Boquimpani-Freitas et al. 2001; Goldberg et al. 2007; Martins and Fabio 2005; Travassos 1925, 1931; Vicente et al. 1991), Ecuador (Dyer and Altig 1976, 1977; McAllister et al. 2010a), Guyana (McAllister et al. 2010d) and Peru (Bursey et al. 2001).

Remarks: *R. ornata*, *H. binotatus* and *H. phyllodes* represent new host records for *Cosmocerca brasiliense*. Anchieta Island is a new locality record.

Cosmocerca parva

Host: *D. brevipollicatus*

Site of infection: large intestine.

Other reported hosts and locality: *Ameerega picta* (Bibron, 1838) (syn. *Epipedobates pictus*) (Cuzco), *Ameerega trivittata* (Spix, 1824) (Rupunini and Ucayali), *Colostethus fraterdanieli* Silverstone, 1971 (Cordilheira Central), *Dendropsophus sanborni* (Schmidt, 1944) (Corrientes), *Edalorhina perezi* (Cuzco), *Elachistocleis ovalis* (Schneider, 1799) (Cuzco), *Hamptophryne boliviana* (Cuzco), *Hypsiboas boans* (Rupunini), *H. fasciatus* (syn. *Hyla fasciata*) (Cuzco), *Hypsiboas raniceps* Cope, 1862 (Corientes), *Hylodes nasus* (syn. *Elosia nasus*) (RJ), *Leptodactylus bufonius* (Corrientes), *L. chaquensis* (Paraguay and Corrientes), *L. elenae* (Paraguay), *L. fuscus* (RJ), *Leptodactylus latinasus* Jiménez de la Espada, 1875 (Corrientes), *L. latrans* (syn. *Leptodactylus ocellatus*) (RJ and SC), *L. leptodactyloides* (Cuzco), *L. marmoratus* (syn. *Adenomera marmorata*) (RJ), *L. mystaceus* (RJ, Cuzco), *L. podicipinus* (RJ), *Leptodactylus* sp., *Odontophrynus americanus* (Duméril and Bibron, 1841) (Corrientes), *Oreobates quixensis* (Ucayali), *Phyllomedusa atelopoides* (Cuzco), *Phyllomedusa hypochondrialis* (Daudin, 1800) (Rupunini), *Physalaemus albonotatus* (Corrientes), *Physalaemus cuvieri* Fitzinger, 1826 (SC), *P. santafecinus* (Corrientes), *P. signifer* (RJ), *P. soaresi* (RJ), *Pristimantis fenestratus* (Cuzco), *P. peruvianus* (syn. *Eleutherodactylus peruvianus*) (Cuzco), *P. toftae* (syn. *Eleutherodactylus toftae*) (Cuzco), *Proceratophrys boiei* (RJ), *Rhaebo glaberrimus* (Günther, 1869) (syn. *Bufo glaberrinus*) (Cuzco), *Rhinella bergi* (Corrientes), *R. crucifer* (Paraguay), *R. fernandezae* (RS, Corrientes), *R. granulosa* (Corrientes), *R. margaritifera* (syn. *Bufo typhonius*) (Cuzco), *R. marina* (syn. *Bufo marinus*) (Cuzco), *Rhinella major* (Müller and Hellmich, 1936) (Corrientes), *R. schneideri* (Paraguay and Corrientes), *Scarthyla goinorum* (syn. *Scarthyla ostinodactyla*) (Cuzco), *Scinax acuminatus* (Paraguay and Corrientes), *Scinax fuscovarius* (Lutz, 1925) (Paragauy and SC), *S. garbei* (Cuzco), *S. ictericus* (Cuzco) and *S. nasicus* (Corrientes).

Geographic range: Argentina (González and Hamann 2006a, 2006b, 2007a, 2007b, 2008, 2009, 2010, 2011, 2012; Hamann et al. 2006a, 2006b, 2009, 2010; Mordeglia and Digiani 1998; Schaefer et al. 2006), Brazil (Fabio 1982; Klaion et al. 2011; Santos and Amato 2010a, 2013; Travassos 1925, 1931; Vicente et al. 1991), Colombia (Sánchez et al. 2010), Guyana (McAllister et al. 2010d), Paraguay (Baker and Vaucher 1984; Masi Pallares and Maciel 1974; McAllister et al. 2010b) and Peru (McAllister et al. 2010c).

Remarks: *D. brevipollicatus* represents a new host record for *Cosmocerca parva*, and this study is the first report regarding helminth fauna of the anuran. Anchieta Island is a new locality record.

Cosmocerca travassosi

Host: *I. parva*.

Site of infection: stomach and large intestine.

Other reported hosts and locality: *Hypsiboas faber* (syn. *Hyla faber*) (RJ).

Geographic range: Brazil (Rodrigues and Fabio 1970; Vicente et al. 1991).

Remarks: *I. parva* represents the second host record for *Cosmocerca travassosi* in South America. *Aplectana membranosa* and *Falcaustra mascula* were the only helminth species previously reported for *I. parva*.

***Cosmocerca* sp.**

Host: *S. hayii* and *C. carvalhoi*.

Site of infection: stomach, small and large intestines.

Other reported hosts and locality: *Eupsophus roseus* (Chile), *Hypsiboas albopunctatus* (DF), *Physalaemus biligonigerus* (Cope, 1861) (syn. *Pleurodema fuscomaculatum* and *Paludicola fuscomaculatus*) (MS), *Pseudopaludicola boliviana* Parker, 1927 (Corrientes), *Rhinella margaritifera* (syn. *Bufo typhonius*) (AM) and *T. typhonius* (syn. *Trachycephalus nigromaculatus* Tschudi, 1838) (MS).

Geographic range: Argentina (Duré et al. 2004), Brazil (Gonçalves et al. 2002; Holmes et al. 2008; Travassos et al. 1939; Travassos and Freitas 1941; Vicente et al. 1991) and Chile (Puga and Torres 1999).

Remarks: *S. hayii* and *C. carvalhoi* represent new host records for *Cosmocerca* sp., and this study is the first report concerning helminth fauna of these anurans. There are 10 South American species of *Cosmocerca*, but characteristics did not allow a species designation for our nematode. Anchieta Island is a new locality record.

Acanthocephala

Cystacanths of undetermined Order, Family genus and species

Host, P% and IMI: *R. ornata* (P = 15%; IMI = 1.0 ± 0), *L. latrans* (P = 50%; IMI = 2.0 ± 1.0), *L. cf. marmoratus* (P = 2.4%; IMI = 1.0), *F. fissilis* (P = 5.6; IMI = 4.0), *M. microps* (P = 33.3%; IMI = 3.0) and *C. carvalhoi* (P = 30.8%; IMI = 4.9 ± 1.6).

Site of infection: muscle of stomach, mesentery, urinary bladder and muscle of body cavity.

Other reported hosts and locality: *Leptodactylus latrans* (syn. *Leptodactylus ocellatus)* (PR) and *Dendropsophus nanus* (Boulenger, 1889) (syn. *Hyla nana*) (Corrientes).
Geographic range: Argentina (Hamann and Kehr 1998) and Brazil (Stumpf 1982).
Remarks: *R. ornata, F. fissilis, M. microps* and *C. carvalhoi* represent new host records for acantocefalans, and this study is the first report regarding helminth fauna of these anurans. For *Leptodactylus* cf. *marmoratus*, the acanthocephalan *Centrorhynchus* sp. has been reported (Fabio 1982). The specimens' proboscises were inverted, so specific identification was not possible. Anchieta Island is a new locality record.

Cestoda
Nematotaeniidae
Cylindrotaenia* cf. *americana
Host, P% and IMI: *H. phyllodes* (P = 33.3%; IMI = 1.0) and *I. parva* (P = 20%; IMI = 1.5 ± 0.5).
Site of infection: small intestine.
Other reported hosts and locality: *Allobates marchesianus* (syn. *Colostethus marchesianus*) (Cuzco), *Atelopus bomolochos* Peters, 1973 (Piura), *Hypsiboas prazinus* (SP), *Rhinella fernandezae* (RS), *R. marina* (syn. *Bufo marinus*) (Colombia and Cuzco), *R. icterica* (PR), *R. margaritifera* (Ucayali), *R. schneideri* (Paraguay), *Scinax pedromedinai* (Cuzco) and *Telmatobius jelskii* (Peters, 1873) (Lima).
Geographic range: Brazil (Madelaire et al. 2012; Santos and Amato 2010a; Stumpf 1981), Colombia (Brooks 1976), Paraguay (McAllister et al. 2010b) and Peru (Bursey et al. 2001; Iannacone 2003a, 2003b; McAllister et al. 2010c).
Remarks: *H. phyllodes* and *I. parva* represent new host records for cestodes. Anchieta Island is a new locality record.

Prevalence of *Batrachochytrium dendrobatidis* in Pond-breeding Amphibians of the Fall Line Sandhills Region of Georgia, USA

The Fall Line Sandhills region of Georgia, USA is an area of high herpetofaunal diversity (Graham et al. 2010), with over 30 amphibian species documented in the region (Jensen et al. 2008). Over a dozen of these are known to occur on the ~355-ha Fall Line Sandhills Wildlife Management Area (FLSWMA) in Taylor Co., Georgia (32.578298°N, 84.269315°W; WGS 84), including the Gopher Frog (*Lithobates capito*) and Striped Newt (*Notophthalmus perstriatus*). The Gopher Frog and Striped Newt are two of Georgia's rarest amphibians, known from only a few sites in the state (Jensen et al. 2008). The emergent infectious disease chytridiomycosis, caused by the fungus *Batrachochytrium dendrobatids* (*Bd*), is still not well understood despite having been implicated as factor in local and global amphibian declines (Fisher et al. 2009; Rosenblum et al. 2013). This pathogen has been detected at numerous sites in the southeastern United States, including Georgia (Green and Dodd 2007; Hill et al. 2011; Hossack et al. 2010; Rothermel et al. 2008; Timpe et al. 2008). Our goal was to determine *Bd* prevalence at a single site within the FLSWMA over multiple years during late winter and spring breeding events. The study site experienced drought conditions in 2011 and 2012 with the focal pond completely drying down in the spring of both years and not refilling until the following winter. The pond retained water through most of 2013. Here we describe prevalence of *Bd* infection over these natural cycles of pond-filling rains and droughts from 2011–2013.

We conducted visual encounter surveys from February–April 2011 (five), February–March 2012 (three), and in February–March 2013 (two). In 2011, surveys ended with the April sampling due to complete pond drying. The pond almost completely dried by early April 2012, thus sampling ended in March of that year. Although the pond remained full through the spring of 2013, surveys were concluded following the March sampling. Sampling was biased toward the most readily collected species during each survey, though all individuals of any species captured were sampled for *Bd*. All surveys took place in and along the edges of a large ephemeral pond on the FLSWMA. The pond serves as a breeding site for a number of amphibians (12+ species) including *Lithobates capito* and *Notopthalmus perstriatus,* which are both protected in Georgia (Jensen et al. 2008). We captured individuals by dip net or by hand within the pond or within 2 m of the water's edge. Only metamorphosed amphibians were sampled, with the exception of one paedomorphic *N. perstriatus*. After capture, individuals were placed singly into Ziploc® plastic bags for a period not exceeding 12 hours for on-site processing. A new pair of powder-free nitrile gloves was worn while processing each animal during all sampling efforts. Field equipment was disinfected between surveys (Miller and Gray 2009).

Following survey completion, individuals were swabbed for *Bd* (Pessier and Mendelson 2010). Swabs were placed into individually numbered plastic vials with one drop of 95% ethanol for storage and shipped to the diagnostic lab at the College of Veterinary Medicine at North Carolina State University, Raleigh. Each sample was processed using *Bd*-specific real-time Taqman (Applied Biosystems, Foster City, CA) Polymerase Chain Reaction (Boyle et al. 2004).

In total, we sampled 368 amphibians between 2011 and 2013. In 2011 127 amphibians representing seven anuran and two caudate species were sampled, with *Bd* being detected in 48 samples from four species, including the Striped Newt (*N. perstriatus*). (Table 1). No evidently diseased animals

TABLE 1. Samples collected per species from 2011–2013 for *Batrachochytrium dendrobatidis* (*Bd*) at Fall Line Sandhills Wildlife Management Area in Taylor County, Georgia, USA.

Species by year	No. *Bd*-Positive/ Total Sampled
2011

2013 Total	5/99
Total for 2011–2013	88/368

were encountered. In 2012, 142 samples were collected from seven anuran and two caudate species, of which 35 samples representing four species were *Bd*-positive (Table 1). Again, all specimens appeared outwardly healthy, although four individuals showed mild ventral redness or small lesions. In 2013, 99 samples were collected from seven anurans and one caudate species, with five samples testing positive for *Bd* (Table 1). Ten specimens showed some mild ventral redness and/or tiny lesions.

Although some opportunistic sampling has occurred in previous years (Timpe et al. 2008 ; Hill et al. 2011), this study represents the first concerted multi-year effort to determine *Bd* prevalence within the Fall Line Sandhills region of Georgia. Our results indicate that *Bd* is quite prevalent in several species at FLSWMA. While some individuals exhibited small lesions or slight ventral redness (N = 18), none exhibited other obvious symptoms of chytridiomycosis. Of those with lesions or ventral redness, only one tested positive for *Bd*. Although we did not test for the presence of ranaviruses, the redness and lesions observed did not appear consistent with those described for ranaviral disease (Gray et al. 2009) and no individuals showed signs of morbidity. The prevalence of *Bd* appeared to be lower in 2013 when all potential breeding ponds at FLSWMA were full and the focal pond had larger boundaries than in either 2011 or 2012. Perhaps this was a result of more available breeding or calling sites, which would reduce any potential crowding effect within the pond (see Longo et al. 2010). Lower *Bd* prevalence in 2013 may also be related to sampling bias, as the species with the highest overall *Bd* occurrence during the first two years (*A. gryllus*) was collected in lower numbers than in previous years.

Acknowledgments.—Financial and logistical support for this study were provided through Atlanta Botanical Garden, North Carolina State University's College of Veterinary Medicine, Zoo Atlanta, Georgia Department of Natural Resources Wildlife Resources Division, the generosity of A. Fusaro and B. Everrett, and the Association of Zoos and Aquariums' Amphibian Taxon Advisory Group. Samples were collected under permits from the Georgia Department of Natural Resources. Laboratory assistance was provided by K. Gore and M. Suyemoto. The following assisted with sample collection and preliminary review of this manuscript: J. Jensen, J. R. Mendelson, III, J. Stabile, M. Dave, and S. Greenspan.

Occurrence of the Chytrid Fungus *Batrachochytrium dendrobatidis* in Amphibians in Illinois, USA

Several reports have documented the occurrence of *Batrachochytrium dendrobatidis* (*Bd*) in Illinois (Lannoo et al. 2011; Steiner and Lehtinen 2008; Talley et al. 2011) but chytridiomycosis has not been implicated in any declines within the State. Efforts to sample for *Bd* continue to be of importance in order to provide a complete understanding of this emerging infectious disease.

We sampled amphibians at 13 lentic habitats throughout Illinois, USA in the winter and spring of 2011 for prevalence of *Bd*. We swabbed 11 different species using a variety of capture methods; adult salamanders were captured in minnow traps; adult and juvenile frogs were captured by hand by placing a clean plastic zipper bag in front of the individual and coaxing them to jump into the bag; larvae were collected in a similar manner except that the bag was placed in the water so that the larva swam into the bag. Amphibians were processed on site and released at the completion of the survey.

We swabbed adult and juvenile anurans by coaxing the animal to the top of the bag, gently grasping the hind leg through the plastic bag, then opening the bag. As the animal tries to escape through the opening it presents itself for thorough swabbing. We used a new pair of lab gloves to remove and hold adult and larval salamanders and larval anurans for swabbing. Swabbing technique followed standard protocols for all salamanders and adult anurans (Skerratt et al. 2008). For larval anurans, only the keratinized mouthparts were swabbed. We stored swabs at room temperature in 70% ethanol in pre-labeled individual cryovials. Upon arrival in the laboratory, samples were stored at -20°C until testing. Total DNA was extracted using the Qiagen DNeasy Blood and Tissue Kit (Germantown, Maryland) according to the manufacturer's protocol. A nested PCR approach was used to increase specificity and sensitivity of *Bd* detection as described by Gaertner et al. (2009). Nested PCR has been found to be 10-100 times more sensitive than single-round PCR (Garland et al. 2011) and as sensitive as the real-time TaqMan PCR assay (Goka et al. 2009). Each diagnostic PCR run included a positive and a no DNA control. A sample was only deemed positive if both the initial and the secondary PCR amplifications resulted in the appropriate sized amplicon. A number of randomly selected positive samples were sequenced to confirm that the amplified products were in fact from *B. dendrobatidis*.

Overall prevalence was 12.8% for 227 individuals (Table 1) and averaged 20.9 % across the 13 sites. None of the amphibians sampled displayed symptoms indicative of chytridiomycosis such as skin lesions or discoloration (Berger et al. 1998; Pessier et al. 1999; Rachowicz and Vredenburg 2004). At one site, Cattail Slough, both the individuals swabbed tested positive for *Bd*. Eliminating the Cattail Slough results reduces the average site prevalence to 14.3%. The remaining sites ranged from 6.7% to 42.9% (Table 1). Eleven species of amphibians were swabbed (Table 2) with a prevalence of 6.9% for salamanders (N = 72) and 15% for anurans (N = 155). *Ambystoma platineum* and *A. tigriunum* were the only species that did not have at least one individual test positive for *Bd*.

Prevalence of *Bd* in all animals swabbed in this study is similar to results from previous surveys of amphibian populations of Illinois and neighboring Midwestern states (Kinney et al. 2011; Lannoo et al. 2011; Steiner and Lehtinen 2008). Due to the opportunistic nature of the study, sample sizes are too small to get an accurate determination of prevalences for each pond or each

species. However, these results reinforce the notion that *Bd* occurrence is widespread throughout Illinois and across species lines. This is the first published record of *Bd* for small-mouthed salamander *Ambystoma texanum* and eastern narrow-mouthed toad *Gastrophryne carolinensis* (Olson et al. 2013). Additionally, 11 of the 29 positive samples were collected in late February and early March with sampling date temperatures varying from -3°C (daily low) to 7°C (daily high). Previous studies have shown a strong correlation between seasonality and *Bd* prevalence with detection rates higher in the spring and lower in the summer (Kinney et al. 2011; Kriger and Hero 2006; Lannoo et al. 2011). This suggests that individuals might be able to clear infection as the summer progresses and temperatures increase (Richards-Zawacki 2009; Rowley and Alford 2013; Woodhams et al. 2003). However, it is unclear what happens to *Bd* prevalence during the winter, as these surveys are conducted during the warmer months (March to October) when amphibians are most active. Do infection rates increase dramatically in early spring as temperatures increase? Is the fungus able to re-infect during the winter as a result of a suppressed immune response (Maniero and Carey 1997; Raffel et al. 2006) in overwintering amphibians? Further research is necessary to answer these questions, but this study shows that *Bd* is present during winter months.

Acknowledgments.—We thank J. C. Crawford, E. J. Kessler, A. R. Kuhns, J. M.

Sudden Mass Die-off of a Large Population of Wood Frog (*Lithobates sylvaticus*) Tadpoles in Maine, USA, Likely Due to Ranavirus

Starting in early April 2013, a 0.23-ha spring-fed, fish-free pond in Brunswick, Maine, USA (43.919°N, 70.040°W) was informally surveyed at least every other day until the end of August. The first Wood Frogs (*Lithobates sylvaticus*) appeared at the pond on 11 April; three days later the adult frogs numbered several thousand, mostly males. On 16 April we counted 550 Wood Frog egg masses, with an average clutch size of ca. 600 eggs. All adults left the pond within several weeks. Based on counts from photographs of tadpoles swimming near the surface of the pond taken in late May, we estimated that there were more than 100,000 Wood Frog tadpoles. The main predator of Wood Frog eggs at this site, the freshwater leech *Macrobdella decora*, was notably scarce in 2013 compared to most years, which may have contributed to the unusually large tadpole densities in May and early June. At 1600 h on 14 June 2013, we noted huge densities of tadpoles. Twenty-one hours later, on the afternoon of 15 June, a few surviving tadpoles were observed swimming slowly near the pond surface, but none was found alive by the end of the day. Tadpole carcasses were present on the pond bottom (1–2 m depth) at a density roughly estimated at 1300/m^2 around the entire 210-m perimeter of the pond (2250 m^2 area), based on qualitative observations and detailed counts from photographs at several haphazardly selected sites (Fig. 1). Assuming that all of the Wood Frog

FIG. 1. Dead Wood Frog tadpoles on the bottom of a pond in Brunswick, Maine showing the representative density (ca. 1300/m^2) along the entire 210 m-perimeter of the pond on 15 June 2013.

FIG. 2. Dead and dying Wood Frog tadpoles showing hemorrhages in their well-developed legs and around their throats, as well as skin shedding. Tadpoles were photographed on the afternoon of 15 June 2013.

mortality was restricted to within 1 m of the shore and using a more conservative estimate of 1000 dead tadpoles/m^2, more than 200,000 tadpoles died in less than one day. Dead tadpoles had hemorrhages in their well-developed legs and around their throats (Figs. 1, 2). Skin sloughing was also observed on both dying and freshly dead tadpoles (Fig. 2). Repeated sampling of the pond through early September revealed no Wood Frog tadpoles.

During the die-off, there were no obvious stressors other than possible overcrowding. During the second week of June, White Pine (*Pinus strobus*) pollen had covered much of the pond; Wood Frog tadpoles formed especially dense congregations in the few pollen-free areas. Otherwise, weather conditions over the two-day period were typical for the season, with daily highs 23–25°C. It was sunny and there was no precipitation.

No other species of amphibian or reptile appeared diseased or experienced noticeable mortality. In informal censuses through September, densities of adult and larval Green Frogs (*L. clamitans*), Grey Treefrogs (*Hyla versicolor*), Spring Peepers (*Pseudacris crucifer*), Spotted Salamanders (*Ambystoma maculata*), and Eastern Newts (*Notophthalmus viridescens*) appeared to be unaffected. Bullfrogs (*L. catesbeianus*), which were scarce before the Wood Frog die-off, continued to be present all summer. Adult Painted Turtles (*Chrysemys picta*) were also apparently unaffected. Considering the isolation of the pond and the fact that we found no carcasses of other amphibian and reptile species and their population densities appeared to be unaffected, chemical contaminants or other human-caused stressors seem unlikely causes of the sudden die-off of Wood Frog tadpoles. In April 2014, the density of Wood Frog egg masses was normal, and on 3 June 2014, almost one year after the die-off, tadpoles seemed abundant and healthy.

Four freshly dead tadpoles were haphazardly collected on 15 June, frozen at –20°C, and submitted to the University of Tennessee Center for Wildlife Health. Given that gross signs were indicative of ranaviral disease (Miller et al. 2011), we tested for infection by this pathogen using real-time quantitative polymerase chain reaction (qPCR). Portions of the liver and kidney were removed from each tadpole, gDNA was extracted and quantified, and real-time qPCR was performed on a tissue homogenate using identical procedures as Richter et al. (2013). We used an ABI 7900 Real-time PCR System, and amplified and tested for a 70-bp of the major capsid protein of ranavirus, because this pathogen is frequently associated with die-offs of wood frog tadpoles (Greer et al. 2005; Harp and Petranka 2006; Brunner et al. 2011; Miller et al. 2011). A standard curve developed from our PCR system was used to predict the quantity of virus (plaque-forming units, PFU) in 0.25 μg of gDNA. Four controls also were run with samples: DNA grade water, negative and positive tadpoles (*Lithobates sylvaticus*), and an FV3-like virus grown in cell culture (GenBank accession no. EF101698; Miller et al. 2007). All four tadpoles tested positive for ranavirus infection. Virus concentrations in the liver-kidney homogenate were between 10 and 115 PFU per 0.25 μg of gDNA (Table 2).

To our knowledge, this is only the second published account and location of ranavirus-associated mortality in Maine, and the biggest and most sudden mortality event reported in the region. The first report of ranavirus in Maine was in Acadia National Park (Gahl and Calhoun 2008; Gahl and Calhoun 2010). Die-offs from ranavirus have been reported from New Brunswick, Canada, and many states in the eastern United States (Miller et al. 2011). Assuming that this die-off was caused by the ranavirus we identified, this would be the largest and most rapid event reported in amphibians. Increasing surveillance for ranavirus and estimating population impacts are important conservation directions (Gray and Miller 2013).

TABLE 1. Results of real-time qPCR estimating the quantity of ranavirus from four Wood Frog tadpoles. Ct = qPCR cycle threshold values (mean of two test runs); Concentration = PFU (plaque-forming units) of ranavirus per 0.25 micrograms of gDNA.

Specimen number	Ct	Concentration
1	27.05	24.55
2	28.47	9.98
3	24.62	115.00
4	25.03	88.83

Prevalence of the Amphibian Chytrid Fungus among Zoo and Pet Store Collections in the Northeastern United States

Recent studies suggest that the amphibian trade has promoted the global transmission of the amphibian chytrid fungus, *Batrachochytrium dendrobatidis* (*Bd*) (Fisher and Garner 2007; Goka et al. 2009; James et al. 2009; Farrer et al. 2011), which is a pathogen implicated as a cause of global amphibian declines (Berger et al. 1999; Daszak et al. 1999; Skerratt et al. 2007; Kilpatrick et al. 2010). In particular, pet shops and zoos constantly acquire and exchange animals depending on their needs and exhibitions, making amphibian collections vulnerable to harboring and transmitting *Bd*. For instance, one study determined 28% of amphibians sold in a number of Japanese pet stores were infected with the fungus (Goka et al. 2009) and several studies reported *Bd*-positive samples among zoo amphibians (Longcore et al. 1999; Miller et al. 2008; Jones et al. 2012; Churgin et al. 2013; Goeroff et al. 2013). Despite the role that pet stores and zoos may play in propagating the disease agent, there is a paucity of studies investigating such possibilities in the United States. Thus, the purpose of this study is to enhance the current knowledge about *Bd* infection among traded amphibians in the United States by examining the prevalence of *Bd* in a variety of pet store and zoo amphibian collections.

A large number of pet stores are widely distributed throughout the United States that internationally and domestically import and sell amphibians. For example, Petco Inc. and Petsmart Inc. are the two largest pet store chains, each of which owns over 1000 stores throughout the United States (Petco: available from http://www.petco.com/ [Accessed 19 August 2013]: Petsmart: available from http://www.petsmart.com/ [Accessed 19 August 2013]). These numbers translate into the distribution of on average 40 or more pet stores per state between these two companies alone. It is likely that some pet owners have disposed of dead or alive purchased amphibians into wild habitats, making it possible that alien *Bd* strains carried by pet amphibians (e.g., Goka et al. 2009) can be transmitted to native amphibian populations. Zoos also may serve as a pathway for bringing *Bd* into amphibian collections and possibly into the local amphibian community, as they receive amphibians from a variety of sources. However, many zoos and aquariums have an Association of Zoos and Aquariums (AZA) accreditation, which sets standard procedures for the acquisition and husbandry of animals which should counter the risk of spreading disease (Poole and Grow 2012). These standards should decrease the likelihood of both presence and transmission of *Bd*.

In November 2012, we collected swab samples of 20 adults of four amphibian species from five different pet stores throughout Pennsylvania (three stores) and Massachusetts (two stores). The pet stores from which we sampled animals included several privately owned and recognized chain stores. From pet stores, we sampled 14 *Bombina orientalis* (Oriental Fire-belied Toads, native to the northeastern Asia), two *Lithobates catesbeianus* (American Bullfrogs, native to the eastern USA), three *Hyla cinerea* (Green Treefrogs, native to the southeastern USA), and one *Ceratophrys ornata* (Bell's Horned Frog, native to South America). Additionally, 30 adult amphibians of nine species were tested for *Bd* from a zoo located in Pennsylvania with AZA accreditation in September 2012. From this zoo we sampled three *L. catesbeianus*, three *Pyxicephalus adspersus* (African Bullfrogs, native to the southern Africa), three *Phyllobates terribilis* (Golden Poison Frogs, native to South America), four *Dendrobates tinctorius* (Dyeing Poison Frogs, native to South

TABLE 1. Prevalence of *Bd* infection for each species in zoo and pet store amphibian collections.

Zoo (Z) or Pet store (P)	Species	No. infected / No. swabbed
P	*Bombina orientalis*	0/14
P	*Lithobates catesbeianus*	0/2
P	*Hyla cinerea*	1/3
P	*Ceratophrys ornata*	0/1
		Total (P): 1/20 = 5%
Z	*Lithobates catesbeianus*	3/3
Z	*Pyxicephalus adspersus*	0/3
Z	*Phyllobates terribilis*	0/3
Z	*Dendrobates tinctorius*	0/4
Z	*Rhinella marina*	0/1
Z	*Ambystoma mexicanum*	0/1
Z	*Trachycephalus resinifictrix*	0/6
Z	*Phyllomedusa bicolor*	0/2
Z	*Polypedates otilophus*	0/7
		Total (Z): 3/30 = 10%
		Total infected: 4/50=8%

America), one *Rhinella marina* (Cane Toad, native to Central and South America), one *Ambystoma mexicanum* (Axolotl, native to Mexico), six *Trachycephalus resinifictrix* (Boatman Frogs, native to South America), two *Phyllomedusa bicolor* (Waxy-Monkey Tree Frogs, native to South America), and seven *Polypedates otilophus* (File-eared Tree Frogs, native to the southeastern Asia). In total, 50 adult individuals of 13 amphibian species were analyzed.

Each individual was swabbed five times on the ventral side of each limb and abdominal surface using a cotton-tipped swab. In order to avoid cross contamination, nitrile gloves, together with cotton swabs, were replaced between each specimen. Skin swabs were stored dry in a 2.0-mL screw cap vial and kept in a -20°C freezer until DNA extraction. DNA was extracted from swabs using PrepMan Ultra (Life Technologies, Grand Island, New York, United States) and 1:10 diluted DNA samples for the subsequent PCR assay were prepared. The PCR primers and cycle were determined based on Annis et al. (2004), consisting of an initial denaturation (94°C for 5 min), followed by 30 cycles of replication and final extension (72°C for 10 min). Each cycle consisted of denaturation (30°C for 45 s), annealing (55°C for 30 s), and extension (72°C for 1 min). PCR products were ran on ethidium bromide stained agarose gels using electrophoresis and visualized under UV light. These products included both a positive control from a known *Bd* source and a negative control containing sterile distilled water. Conventional PCR combined with agarose gel electrophoresis was used instead of real-time PCR, as a recent study recommended this technique for studies that require only prevalence data (Garland et al. 2011). PCR and gel electrophoresis were repeated three times for all positive samples to prevent any false negative or positive results.

Four of 50 (8%) amphibians tested positive for the presence of *Bd* (Table 1). Three *L. catesbeianus* from the zoo were *Bd* positive, and one *H. cinerea* from a national chain pet store in Pennsylvania was *Bd* positive. These samples consistently showed positive results in the three replicates of the PCR assays.

Whereas only 8% of individuals and 2 of 13 (15%) species were infected with *Bd*, this could have profound effects on *Bd* transmission given the scale of the amphibian trade. The infection that we found in *H. cinerea* sold at the chain pet store poses a potentially devastating risk, because the species is native to the central and southeastern United States and is a commonly sold pet amphibian in the United States and around the world. For instance, between 1998 and 2002 at least 87,536 Kg of *H. cinerea* were exported from the United States as pets (Schlaepfer et al. 2005). Given the high *Bd* infection rate detected among traded amphibians (Goka et al. 2009; Schloegel et al. 2009), the large vendors and breeding centers responsible for rearing and trading these amphibians, as well as the pet stores themselves, likely have lax regulations and protocols in place to prevent the spread of *Bd*. Additionally, some state regulators have not passed specific laws protecting harvested or imported amphibians, particularly concerning amphibians infected with *Bd* (Wilson 2005). Thus, our results predict that the number and distribution of infected pet amphibians in the United States could be substantial.

The instances of infection in the three *L. catesbeianus* were not surprising, as this species is a globally well-known vector of *Bd* (Garner et al. 2006; Schloegel et al. 2010). Some zoos acquire their amphibians from a variety of sources, including many of the centers responsible for breeding amphibians for the pet trade. The zoo staff revealed that the *L. catesbeianus* individuals examined in our study were obtained from a commercial bullfrog farm (L. Brennan, pers. comm.). Acquiring amphibians from such sources comes with the risk of bringing *Bd* into the zoo collection. Despite no clinical signs of *Bd* infection shown by the *L. catesbeianus*, however, the zoo managed their amphibian collection properly and prevented *Bd* from spreading from those *L. catesbeianus*, which all were kept in the same container. The AZA Amphibian Husbandry Resource Guide details preventative and treatment procedures against *Bd* (Poole and Grow 2012). Although we examined only one zoo, our case exemplifies a quality husbandry standard followed by an AZA accredited institution. Meanwhile, it is important to note that if zoos maintain collections that contain *Bd* as detected in our study, they run the risk of counteracting any sorts of conservation breeding efforts (De Paula et al. 2012).

A study like the present one is important as it disseminates critical information about *Bd* prevalence among zoo and pet store amphibians. Our results suggest that stricter protocols and routine *Bd* screens are warranted to protect traded and captive amphibians from disease infection and transmission. A similar type of protocol was implemented when *Salmonella* infection in humans became prominent due to lenient regulations protecting reptiles in the pet trade, which dramatically decreased the number of reported *Salmonella* cases associated with handling reptiles (de Jong et al. 2005). Continued monitoring on the prevalence of *Bd* among traded amphibians at a larger scale is essential to promote amphibian conservation.

Acknowledgments.—We thank the zoo and pet stores for allowing us to study their amphibian collections. We are also grateful to Mike Huffner, Patrick Calamare, and the rest of our Amphibian Biology class at Bucknell University for their help with this project, and Dede Olson, Linda Weir, and an anonymous reviewer for their valuable comments and suggestions on our earlier draft. The Department of Biology at Bucknell University kindly provided funding for this project.

Prevalence and Spatial Distribution of Frog Virus 3 in Free-Ranging Populations of Northern Cricket Frogs (*Acris crepitans*), American Bullfrogs (*Lithobates catesbeianus*), and Northern Leopard Frogs (*Lithobates pipiens*) in Western Illinois and Wisconsin, USA

Disease is a major contributing factor to amphibian declines (Daszak et al. 1999; Gray et al. 2009). More than 30% of the world's amphibian species are threatened with over 480 species on the critically endangered list (Stuart et al. 2004; IUCN 2009). Such staggering numbers warrant investigations to determine how diseases, such as those caused by ranaviruses, may affect wild animals and their declining populations. Prior to our study, no ranavirus-associated mortality events have been reported in Illinois. However, approximately 800 amphibians, including Green Frogs, Northern Leopard Frogs, and Bullfrogs, were reported to have ranavirus-related deaths in Wisconsin in 2009 (National Wildlife Health Center 2011). Frog virus 3 (FV3), was also first isolated from Northern Leopard Frogs collected in Wisconsin or Minnesota in the early 1960s (Granoff et al. 1965). Due to their lethal nature and threat to declining populations,we set out to explore the prevalence and spatial distribution of ranaviruses in western Illinois and Wisconsin, along the eastern side of the Mississippi River.

For this study, we chose to study an area on the western borders of Wisconsin and Illinois along a major watershed, the Mississippi River. Sample sites were chosen based on accessibility and the presence of large frog populations. We sampled eight sites in Illinois and four sites in Wisconsin in late May and early June of 2011 (Table 1, Fig. 1). We recorded each site with a handheld GPS unit (eTrex Vista, Garmin, Olathe, Kansas) and we used geographic software to analyze the data (ArcMap 10.1, ESRI, Redlands, California). We captured free-ranging Northern Cricket Frogs (*Acris crepitans*) by placing a plastic zipper bag in front of each frog and waiting for it to jump into the bag. We collected American Bullfrogs (*Lithobates catesbeianus*) and Northern Leopard Frogs (*Lithobates pipiens*) using a dipnet. We removed these frogs from the net with a plastic zipper bag. New zipper bags were used for each capture. Within 15 minutes of capture, we performed a physical examination to identify any clinical signs consistent with FV3, including edema, erythema, loss of pigment, ocular and nasal discharge, papules and plaques, epithelial sloughing, hemorrhage, and petechiation. We swabbed the oral cavity, then the cloaca, of each frog using a single cotton-tipped applicator. We immediately stored the swabs in a cooler (1–2°C) or refrigerator (3–5°C), and then transferred them to a –20°C freezer within four days. All animals were released at the site of capture immediately after swabbing and nets were rinsed with pond water between each capture. At the time of the survey, there was no indication that infectious disease was present any of the sites and strict biosecurity of boots and nets was not part of our routine sampling protocol, but have since implemented measures to disinfect gear between sites.

We extracted DNA from the cotton-tipped applicators following the manufacturer's spin protocol for DNA purification from oral swabs (QIAGEN QIAamp® DNA Blood Mini Kit, QIAGEN Inc., Valencia, California). We tested the concentration and purity of the DNA extracts using spectrophotometry (NanoDrop, Wilmington, Delaware) to ensure high quality samples in the face of limitations such as a small sample size and inability to collect and test internal tissues. We performed real-time PCR assays targeting a highly conserved major capsid protein of ranaviruses using sense (AACGCCGACCGAAAACTG) and anti-sense (GCTGCCAAGATGTCGGGTAA) primers and TaqMan-MGB probe (CCGGCTTTCGGGC) from Allender et al. (2013a).

We tested 100 frogs, which included 50 Northern Cricket Frogs (all from Illinois), 25 American Bullfrogs (seven from Illinois and 18 in Wisconsin), and 25 Northern Leopard Frogs (12 in Illinois and 13 in Wisconsin; Table 1). None of the captured frogs showed clinical signs related to ranavirus, but one bullfrog tadpole had signs of a bite wound to the ventral aspect of the tail and one leopard frog had a lesion on the front left leg that appeared to be trauma-induced. This leopard frog tested positive for *Ranavirus* DNA (~2.58×10^6 genome copies), as did one adult male Northern cricket (~3.4×10^3 copies), and one male American bullfrog (~2.5×10^3 viral copies). The overall ranavirus prevalence was 3% (95% CI = 1–9%), and the prevalence in cricket frogs, bullfrogs, and northern leopard frogs was 2% (95% CI = 1–12%), 4% (95% CI = 0–22%), and 4% (95% CI= 0–22%), respectively. The positive cricket and leopard frogs were found in Illinois in different ponds. The positive bullfrog was found in Wisconsin. Three of the 12 sites (Prevalence: 25%; 95% CI = 9–53%) had a positive sample (Table 2).

While our samples were swabs of the oral cavities and cloacas of the frogs, and thus represent environmental samples, we have no reason to suspect that our positive results are from contamination. Brunner and Collins (2009), for instance, found that tiger salamander larvae that died of experimental ranavirus-

exposures had viral titers in their tissues in the millions of copies, such as we found in the Northern Leopard Frog, and earlier in the infection shed hundreds to tens of thousands of viral copies in skin scrapes, similar to the titers we observed in the cricket frog and bullfrog. Even if the positive-testing frogs in our study fed on contaminated material and thus contained high concentrations of viral DNA in their oral cavity or cloaca, it is clear that the virus is present in the environment, if not causing active disease. In previous work, the assay that we used in this study had shown 100% specificity and 83% sensitivity in both oral and cloacal swabs in Red-eared Sliders (Allender et al. 2013b). The effectiveness of the assay supports the possibility of infection of the positive frogs without clear indication of clinical signs. While the DNA purity as measured by the A260/A280 ratio differed between positive and negative samples (mean = 2.04 and 1.79, respectively, with an ideal range of 1.7–1.9), the DNA concentrations were similar indicating that these were true negative results rather than a lack of DNA. Future investigations may determine the presence or absence of an anuran housekeeping gene to increase the negative predictive value of the result.

This study documents FV3-like virus in Illinois and Wisconsin amphibians in 2011, and thus should be included in conservation plans aimed at protecting all susceptible species. There is still a paucity of information on the ecology of this virus in natural settings, but surveillance and prevention is justified in light of these findings. Future investigations should expand the range of species tested, as well as impact this virus has on native wildlife.

Acknowledgments.—We thank the Merial Veterinary Scholars Program for the funding that made this project possible. We would also like to thank D. Wylie and E. Kessler for assistance in the field. Illinois samples were collected under IDNR permit to CAP. The samples in Wisconsin were collected under permit number SCP-WCR-141-C-2011. All animal procedures were approved by the University of Illinois Institutional Animal Use and Care Committee (Protocol number 09029).

Reproductive Biology of the Mona Coqui (*Eleutherodactylus monensis*) in Captivity

The Mona Coqui (*Eleutherodactylus monensis*) is a medium-sized (49.4 mm maximum SVL for females), terrestrial frog endemic to Mona Island, Puerto Rico (Joglar 1998). The Puerto Rican archipelago is home to 17 species of native *Eleutherodactlyus*, however, the Mona Coqui is the only amphibian known to inhabit Mona Island, a small (57 km²) subtropical dry forested island located close to the center of the Mona Passage between Hispaniola and Puerto Rico. *Eleutherodactylus monensis* is currently listed as Vulnerable due to its restricted range (IUCN 2013), emerging amphibian disease, habitat alteration, and climate change (R. Joglar, L. Santiago, and P. Burrowes, unpubl. data). Although the systematics and evolution of the species within the genus *Eleutherodactylus* have been extensively studied, very little is known about their reproduction, ecology, and behavior (Burrowes 2000). Since there is no published information on its karyotype, pattern of activity, call, reproductive biology, or current population status (Joglar 1998), *E. monensis* is probably the least-studied of all the 17 *Eleutherodactylus* species in Puerto Rico. An *ex-situ* captive breeding program for *E. monensis* was started in order to 1) establish a captive assurance population; 2) learn about its reproductive biology; and 3) increase awareness of the global amphibian crisis through the use of an exhibit dedicated to *E. monensis*, amphibian-based zoo events, and publications. Herein we report several aspects of this species' reproductive biology, direct observation of nesting behaviors, as well as challenges with neonate survivorship during this study.

Specimen acquisition and husbandry methods.—In May 2012, five adult male/female pairs were collected from Sardinera, Mona Island, and transported to Albuquerque BioPark Zoo. Females measured an average snout–vent length (SVL) of 37.1 mm (33.3–40.5 mm, SD = 2.5; N = 5), and males 23.4 mm (21.1–25.0 mm, SD = 1.8; N = 5). All specimens underwent a 30-day

quarantine period where they tested negative for the amphibian chytrid fungus (*Batrachochytrium dendrobatidis*) and *Ranavirus*. Specimens were sampled for the amphibian chytrid fungus and *Ranavirus* as per Pessier and Mendelson (2010). All samples were tested at the San Diego Zoo's Institute for Conservation Research Wildlife Disease Laboratories (Allan P. Pessier, DVM, Dipl. ACVP, Associate Pathologist). Appropriate biosecurity measures were taken to prevent pathogen transfer and contamination as recommended by Pessier and Mendelson (2010).

One pair of *E. monensis* were kept per a 30 × 30 × 46 cm terrarium made by ZooMed Laboratories©, model NT-2 (San Luis Obispo, California). Drainage holes were drilled in the bottom of each terrarium and a false bottom consisting of plastic egg crate and plastic mesh was placed 3 cm above the bottom of the tank. The substrate, a mixture of sand, sphagnum moss, and peat moss, was 5 cm deep. Limestone rocks and a bromeliad (*Guzmania* sp.) were placed on the substrate in each terrarium as refugia. An automated rain system was set to mist the enclosures every three hours (eight times during a 24-h period) for ten seconds each interval. All water initially used for the rain system was municipal water run through a filtration system (Whirlpool© [WHED 20] Benton Charter Township, Michigan). Post-filtration pH was 7.8. In early 2013, the water used on these frogs was switched to reverse osmosis filtered water (Whirlpool© [WHER 25]) reconstituted with calcium using dissolved cuttlebone to remove fluoride. Ambient room temperature ranged from 23°C in the evening to 26°C during the day. Fluorescent lights above the enclosures were turned on at 0800 h and off at 1700 h every day to mimic a natural photoperiod. Frogs were fed a rotation of live crickets (*Acheta domesticus*) dusted with Rep-Cal brand (Los Gatos, California) vitamin supplement, fruit flies (*Drosophila hydei*), Blue Bottle House Flies (*Calliphora vomitoria*), termites (*Reticulitermes tibialis*) when available, and pill bugs (*Isopoda* sp.) three times per week.

Reproductive biology.—Very little is known about the reproductive biology of *E. monensis* in the wild, but a single reproductive event was documented on Mona Island in September 2012 (Joglar et al. 2012). Initial observations during our captive study documented that these direct-developing frogs utilize axillary amplexus. Since acquisition, we observed six successful captive reproductive events from three different pairs. Although it has been suggested that *E. monensis* breed year round, similar to other species of *Eleutherodactylus* native to Puerto Rico (Joglar 1998), 83% of nesting activity in our captive population occurred in late summer with three oviposition events in July and two in August. This time of year coincided with New Mexico's wet season, which runs May through September, and there were notable decreases in barometric pressure coinciding with these reproductive events. During the initial stages of mating, the male began vocalizing early in the evening (1700–1800 h) and continued until approximately 0100–0200 h. Based on one previous study involving one female and two males of *E. monensis*, it was documented that both the male and the female frogs aid in digging an oviposition site overnight (Numazawa and Sengoku 2011). We observed similar behavior during our study in which six pairs of frogs spent 7–10 days preparing the nest site. Nest concavities during our study measured approximately 44.6 mm width (38.1–50.8 mm, SD = 4.6; N = 6) and 25.4 mm in depth (24.6–26.7, SD = 0.8; N = 6). The male reduced the frequency and volume of evening vocalization considerably during nest site excavation. Video footage obtained on multiple nights clearly identified the female

PHOTO BY JENNIFER L. STABILE

FIG. 6. Newly hatched *Eleutherodactylus monensis* with MBD.

digging the nest concavity directly next to a bromeliad set horizontally for refugia by rotating and using her rear legs to push out the substrate (Fig. 1). This continued for several evenings, at which time the male would stay near the nest site observing the females' activity. Three to five days into the construction of the nest, the female would leave and the male would continue digging in the same fashion as the female (Fig. 2). These actions were documented using night vision videography (Sony© [HXR-NX70U] Digital HD Video Camera Recorder, Knan Minato, Tokyo). Amplexus occurred within a few days of the male entering the nest concavity. Although it was not captured on film, the egg mass was then covered by the same substrate, post-oviposition, by the following morning. This reproductive behavior occurred on substrates including sand, peat moss, and sphagnum moss. Average number of eggs laid for each clutch during ovipositon was 21 eggs (12–30 eggs, SD = 7.2; N = 7). The eggs were deposited and stacked together with no apparent pattern. Average diameter of eggs at oviposition (Fig. 3) was 5.3 mm (4.7–6.0 mm, SD = 0.3; N = 12). No further parental care was observed from either the male or the female during any of these reproductive events. Incubation period averaged 21 days (13–28 days, SD = 5.8; N = 7). On two occasions and with two different pairs, the female deposited her second egg mass on the same day as the first clutch hatched. The concavity constructed for the second clutch was within 5.1 cm of the previous concavity. The number of eggs to hatch per clutch averaged 16 eggs (3–30 eggs, SD = 9.4; N = 7). The average size of the egg within a few days prior to hatching was 6.9 mm diameter (6.1–7.0 mm, SD = 0.2; N = 13 [Fig. 4]). Upon hatching, all offspring were separated into groups of three and placed into 1-liter clear plastic deli cups with holes (4–5 mm) punched into the lids. Average SVL of post-hatching individuals (Fig. 5) was 8.6 mm (8.2–9.7 mm, SD = 0.4; N = 48). Hatchlings were kept on moist sphagnum moss and misted daily with the reverse osmosis filtered water, reconstituted with calcium. Hatchlings were fed a daily diet of two collembolan species and flightless fruit flies (*Drosophila melanagaster*) dusted with Rep-Cal brand vitamins until they were large enough to consume other commercial invertebrates such as crickets (*Acheta domesticus*), large fruit flies (*D. hydei*), termites (*Reticulitermes tibialis*) and pill bugs (*Isopoda* sp.).

Notably, on two occasions females were observed consuming several eggs when left in the enclosure. After witnessing these actions, we began removing the female from the enclosure. We kept the male in the enclosure with the egg mass to look for parental care as documented in *E. cooki* (Burrowes 2000), but which was not witnessed during any of the six reproductive events. Another observation was the duration the pair of adult frogs spent working together on the nest site. During this study, we have documented both male and female frogs digging the concavity between 7–10 days. In this time period, the male greatly reduces vocalization to only a few short clicks in the evening, as opposed to the rapid, frequent clicks encountered prior to nest excavation. This behavior indicates that this species might not significantly advertise call during the duration from nest building through oviposition. More work needs to be done to study this potentially unique reproductive characteristic.

Challenges with neonate survivorship.— In 2012, the first year of this study, 100% of the offspring died within the first 3 months of hatching. Since changing the water filtration system to reconstituted reverse osmosis water, we have had two successful reproductive events yielding 52 hatchlings, with only one froglet mortality by the time of ms. submission (December 2013). Froglet mortality was found to be due to severe metabolic bone disease (MBD), possibly caused by fluoride exposure, inhibiting the absorption of calcium during egg development (A. Pessier, pers. comm.; Fig. 6). Diet was ruled out as a potential cause of mortality due to the variety of invertebrates and supplementation schedule used for both the adult frogs and offspring. All municipal water was originally run through a filtration system that did not remove fluoride (F- 0.38 mg/l reporting limit .05; 31.59 Ca mg/l). In 2013, all water used on these frogs went through a reverse osmosis filter to remove fluoride and was then reconstituted with calcium (F- 0.00 mg/l reporting limit .05; Ca 27.4 mg/l). We feel that the water change made in 2013 had a direct result in our higher success rate with neonate survivorship.

Acknowledgments.—We thank the ABQ BioPark Zoo Department of Herpetology, the Department of Biology at the University of Puerto Rico–Río Piedras Campus, CREST–CATEC, Department of Natural and Environmental Resources (DRNA), and Proyecto Coquí for their support during this study. Live specimens were collected from Mona Island, Puerto Rico under DRNA permit number 2012-IC-039.

Successful Captive Breeding of *Necturus beyeri* through Manipulation of Environmental Cues and Exogenous Hormone Administration: a Model for Endangered *Necturus*

Necturus is a genus of aquatic salamanders endemic to the eastern United States. Over half of amphibian species demonstrating preference for a "flowing water" environment have populations in rapid decline (Stuart et al. 2004). Presently, there are at least five recognized species of *Necturus* (Viosca 1937; Neill 1963; Ashton 1985; Guttman et al. 1990; Bart et al. 1997). The International Union for the Conservation of Nature (IUCN 2013) categorizes *N. alabamensis* as endangered and *N. lewisi* as near threatened, with the other three species (*N. maculosus*, *N. beyeri*, and *N. punctatus*) classified as least concern. Although *N. maculosus* has served in laboratory research for over a century (DeNardo 1995), its use has been supported by capture of individuals from the wild, with only a single incident of captive reproduction formally reported in the literature (Raffaelli 2000). Breeding species with a dedicated aquatic life history, cryptic activity patterns, and highly seasonal reproductive nature like *Necturus* can be challenging *ex-situ*. To expand reproductive research of such taxa, with the intent of applying successful results to propagation efforts for the endangered *N. alabamensis*, a surrogate or model species of "least concern" should be established. Given the phylogenetic relationship of *N. alabamensis* to *N. beyeri*, similar biological and habitat requirements and size, we hypothesized that *N. beyeri* could serve as an effective model species (Guttman et al. 1990; Neill 1963).

As in many other salamanders, *Necturus* reproduce via internal fertilization, with the males producing spermatophores (Selmi et al. 1997; Sever 1992; Sever 2002). Male *N. maculosus* display swelling of the cloaca from September–April, with peak cloacal protuberance observed in December–March (Bishop 1926). In male *N. beyeri*, timing of peak cloacal swelling is shifted by one month earlier (Cagle 1954; Shoop 1965), presumably due to the lower latitude in which this species lives. Motile sperm have been observed in the Wolffian ducts of *N. maculosus* and *N. beyeri* as early as December (Baker 1963; Shoop 1965). The transfer of spermatophores from male to female *Necturus* occurs several months prior to oviposition (Sever 2002; Shoop 1965). Nest size varies depending on species (Eycleshymer 1906; Smith 1911; Bishop 1926; Shoop 1965), and attempts to rear offspring *ex-situ* from eggs collected from the wild has been met with low success (Shoop 1965).

Administration of exogenous hormones has proven effective for captive breeding of many amphibian species, most notably anurans (Roth and Obringer 2002; Browne and Zippel 2007; Kouba et al. 2009). Limited information exists in this regard for salamanders. Gametes have been collected after hormone injection of male (Bishop 1932) and female (Fitch 1958) *N. maculosus*. Extract of whole sheep pituitaries administered to wild-caught males during the breeding season resulted in spermatophore deposition (Bishop 1932). Infertile eggs have been deposited following treatment of female *N. maculosus* with chorionic gonadotropin (CG) and pituitaries from *Lithobates pipiens*; however, such treatments produced variable responses and mortalities. These same methods did not stimulate *N. beyeri* to deposit eggs (Shoop 1965). More recently, researchers have been able to manually collect sperm and strip eggs from the axolotl (*Ambystoma mexicanum*) using Ovopel® pellets and human chorionic gonadotropin (hCG; Mansour et al. 2011).

The objectives of this project were to 1) establish a captive population of *N. beyeri* at the Center for Conservation and Research of Endangered Wildlife (CREW) at the Cincinnati Zoo & Botanical Garden to serve as model research species for *N. alabamensis*; and 2) manipulate environmental cues and administer exogenous hormones to stimulate successful breeding, production, and rearing of offspring. Biotic and abiotic water conditions were adjusted to model *in-situ* seasonal changes, including manipulation of artificial lighting to mimic the natural day/night cycle throughout the year. Finally, we administered luteinizing hormone-releasing hormone (LHRH) to induce a pituitary response in male and female *N. beyeri* to promote spermatophore deposition and ovulation/oviposition over a 2.5-yr period.

Husbandry and feeding.—In January 2011, 1 male and 2 female *N. beyeri* (ISIS #s CWF12-02629, CWF12-02620, CWF12-02601) were accessioned into a glass tank measuring 91.44 × 45.72 × 30.48 cm at CREW (Fig. 1). As animals were brought in during the middle of their normal breeding season, we will hereafter refer to Yr 1 as Fall 2011–Spring 2012 and Yr 2 as Fall 2012–Spring 2013. The tank was

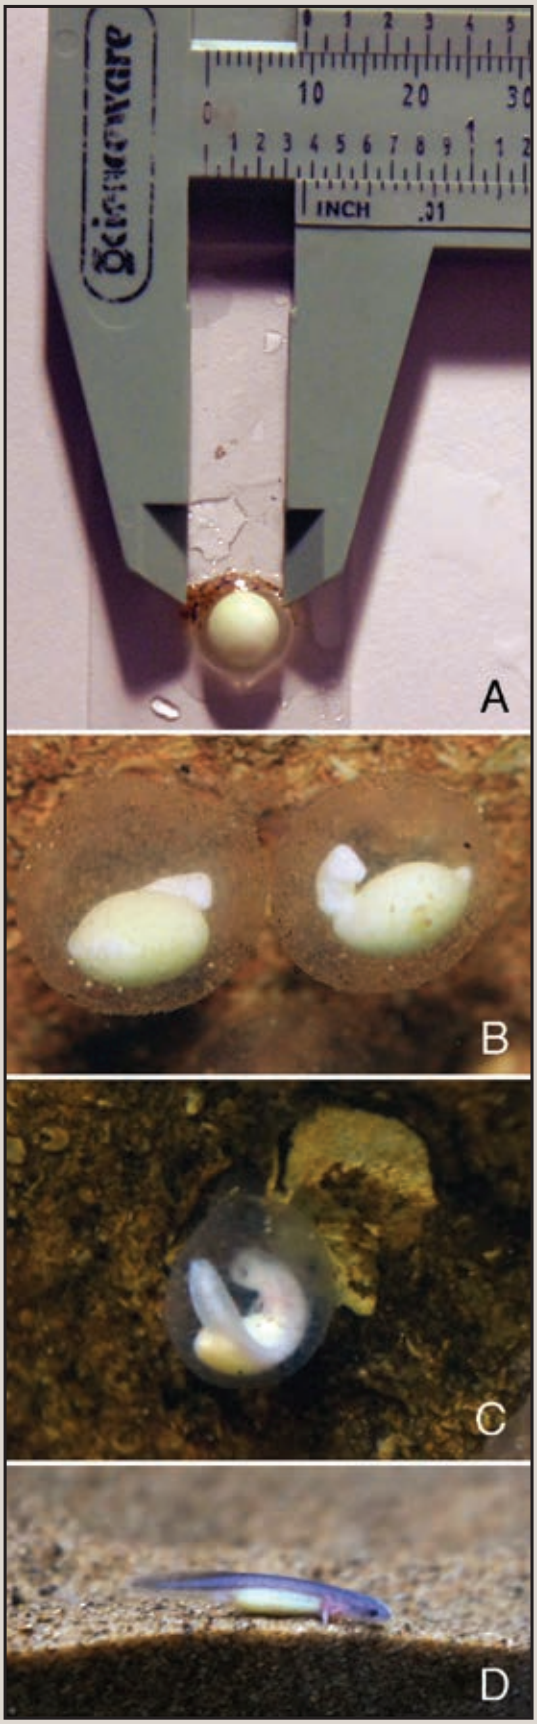
connected to a water chiller and UV sterilization unit (Model 2606; Current USA, Vista, California) via PVC pipe (2.54 cm diameter, sch 40). Filtration was achieved through a carbon spunfiber filter (GE FXUSC). Substrate consisted of extensively weathered quartz sand collected from Bankhead National Forest, Alabama. Sandstone, slate and limestone slabs were provided as cover objects for the animals. Additionally, red oak and white walnut bark, extensively soaked in deionized (DI) H_20 were provided. Weekly, 10–15% of tank water was removed and exchanged with (DI) H_20. In the fall, leaves (1/gallon, not exceeding 10 leaves) were introduced and allowed to partially decay to about half the starting area. Species included oak, tulip poplar, and sycamore.

Diet consisted of frozen-thawed shrimp (*Litopenaeus setiferus*) and live redworms (*Eisenia fetida*). Seasonally, as animals became more active (shortened day length/colder temperature), live Greenside Darter (*Etheostoma blennioides*), Black-spotted Topminnow (*Fundulus olivaceus*), Silver Shiner (*Notropis photogenis*), and Creek Chub Minnows (*Semotilus atromaculatus*) were provided after being treated with parasite tablets (Tetra™, ParasiteGuard®, Blacksburg, Virginia) 30 days prior to being offered. An infrared day/night camera system (#68332; Bunker Hill Security, Camarillo, California) recorded tank activity continuously. Animals were housed together, with the exception of the male being removed on 31 March 2013 in preparation for potential egg laying.

Temperature and photoperiod.—Water temperature was manipulated to mimic natural conditions. During Yr 1, the average water temperature was 18°C, with seasonal low and high temperatures of 12°C and 22°C occurring on 1 January and 25 July 2012, respectively. In Yr 2, the average water temperature was 16°C, with seasonal low and high temperatures of 11°C and 19°C achieved on 3 January and 6 April 2013, respectively. From January 2011 to April 2012 a fluorescent light strip mounted 25.4 cm from the surface of the water tank was set to a timer matching natural seasonal sunrise and sunset times. In May 2012, the fluorescent lights were replaced with LEDs (IKEA, #16670) powered directly by a south-facing, 45-watt solar panel set providing local seasonality and variable light intensity (i.e., light output corresponded to time, position of sun, cloud cover). The system was designed to operate at 45W of output (minus system loss of 5% to wiring and panel age). A custom 12V charge controller limited output to 14V max, so the LED would show most intensely as the conditions dictated (ie, midday sun, summer, no clouds). As the angle of incidence of light to the PV panels changed (sunrise, sunset, rain or clouds), power generation dropped off and the LEDs responded proportionally. The system had no extra power generation capacity and the room was completely free of any other light source. The result was a novel lighting system that responded to real-time variation in daylight intensity and day length variation.



Anesthesia, exogenous hormone, and ultrasonography.—All procedures were approved by the Cincinnati Zoo and Botanical

Garden's Institutional Animal Care and Use Committee (IACUC; 11-110). Prior to administration of exogenous hormones, animals were anesthetized in 0.5g/L (Fellers et al. 1994) buffered (0.5M $NaHCO_3$) Tricaine Methanesulfonate (Western Chemical, Ferndale, Washington). Two 4.1-L rectangular containers (Rubbermaid™ TakeAlongs® #7F55) with air stones (2.54 cm) and pumps (Fusion 200 Air Pump) were used for anesthetic procedures. Animals were handled with non-powdered, pre-moistened nitrile gloves (Kimberly Clark; Cole-Parmer, Vernon Hills, Illinois). Transport, anesthetic, and recovery tanks contained original tank water. Induction was determined by failure of the animal to respond to being turned over. Animals were removed from the induction tank and held on a disposable piece of surgical drape (JorVet, Jorgensen Laboratories, Loveland Colorado) with the body tilted at a 45° angle (head down) for intraperitoneal (IP) injection (27 gauge needle) in the posterior quadrant of the abdomen. Animals were injected with [des-Gly10, D-Ala6]-LH-RH ethylamide acetate salt hydrate (L4513, Sigma Aldrich, St. Louis, Missouri) in sterile H_20 (Table 1). Skin and gills remained moistened during injection, after which animals were placed in a recovery tank. Once animals were moving normally and regained a righting response, they were returned to their original tank. The average induction time to IP injection was 6 min 38 sec (Table 1). Conscious control of gills, body, and legs were regained at an average of 14 min 21 sec, 20 min 30 sec, and 24 min 39 sec, respectively (Table 1).

An Aloka 500 ultrasound (Aloka, Wallingford, Connecticut) connected to a portable digital video recorder (MediaMate, Blue Raven, Wilmington, Massachusetts) and a 7.5-mHz linear array probe was used for transabdominal ultrasonographic examination of females during Yr 2 (31 March 2013). Ultrasound was performed on the LHRH-treated female (CWF12-02620) while she was under anesthesia. The untreated female (CWF12-02601) was manually restrained for the procedure. Ultrasound revealed multiple eggs of similar size (5–6 mm) in both females (Figs. 2A, B).

Spermatophore deposition.—Despite evidence of cloacal swelling, no spermatophores were deposited either prior to or following LHRH administration of the male in Yr 1. During Yr 2, the male exhibited cloacal swelling beginning 8 November 2012. The act of spermatophore deposition was captured on video 33 days (4 January 2013) following LHRH administration. However, evidence of spermatophore deposition, as observed by the presence of mucous strands, was noted 27–35 days post-injection (29 December 2012, 31 December 2012 and 6 January 2013). The spermatophore deposited on 4 January 2013 was removed from the tank within 30 min of deposition, measured (approx. 12 mm diameter; Fig. 3A), and examined under a microscope. Tightly bound aggregates of sperm were observed, but individual sperm motility was not detected (Fig. 3B).

Oviposition, embryonic development, and hatching.—Although it was suspected one female was gravid, no eggs were deposited during Yr 1. In Yr 2, both females deposited eggs over a three-day timeframe (4–6 April 2013). The untreated female (CWF12-02601) was the first to deposit, quickly followed by the treated female (CWF12-02620). Eggs were deposited on the underside of wood (CWF12-02601; N = 33) and stone (CWF12-02620; N = 25). Eggs that began to show a cloudy or swollen appearance were removed from the nest by the attending female and floated loose in the tank or were consumed. Unconsumed loose eggs were manually removed from the tank. Over time, fertilized eggs changed in shape from round (Fig. 4A) to

compact and ovoid in appearance. Around day 31, embryos were visible inside the eggs (Fig. 4B). Females were allowed to guard and tend nests up to day 33 post-oviposition. After that time, females began to show aggression and predate conspecific nests. To minimize risk of injury to adults and the developing embryos, females were removed from the tank and housed individually. Thereafter, the stone and wood structures containing N = 6 and N = 1 developing embryos, respectively were adjusted to provide a clear view from the front of the tank. Efforts were taken to remove (using a restricted 1.27 cm Tygon® tube) sand and organic material that became attached to the eggs, in order to emulate brooding female behavior, but the siphon-generated suction was observed to be too aggressive and risked pulling eggs off their supporting structure. Additional filtration and manual cleaning of the tank was undertaken to preemptively remove organic particles before they could find their way to the eggs. The one remaining embryo from the untreated female developed normally up to day 50, after which the embryo took on a swollen appearance, was deemed nonviable and subsequently removed from the tank. After day 50, a piece of panty hose was placed over the outtake valve to ensure hatched larvae would remain safe. One of the six embryos became dislodged from the stone structure and was placed in a 1000-mL sterile glass beaker in the tank. At day 55, embryo movement was detected (Fig. 4C). Hatching (N = 6) occurred 73–75 days post-oviposition. Hatched larvae were maintained in the glass beaker until day 77 before being released into the larger tank (Fig. 4D).

Although global efforts to save amphibians have intensified, so have threats to their survival (Stuart 2004). The cool, flowing water habitat (Stuart et al. 2004) preferred by *Necturus* spp. has declined across many regions of the United States. Despite this, several populations *(N. maculosus*, *N. punctatus*, and *N. beyeri)* appear secure, if not abundant (IUCN 2013). However, there is strong evidence to support declining populations of *N. lewisi* and *N. alabamensis* (IUCN 2013). A number of North American zoological institutions hold *N. maculosus* and *N. beyeri*, but the other three species have either not been held or are held at only a few institutions and in small numbers. Several captive breeding programs for endangered amphibians have benefited from the application of husbandry and reproductive techniques developed in more common species (Obringer et al. 2000; Uteshev et al. 2012). Through this project, *N. beyeri* was established as a potential surrogate species for captive research efforts aimed at one of the most endangered salamander species in North America, *N. alabamensis*.

Because *Necturus* demonstrate reproductive seasonality *in situ*, seasonal changes in water temperature and day length occurred *ex situ* in an effort to mimic the natural environment and stimulate reproduction. Comparable seasonal temperature extremes were achieved over the 2.5-Yr period. The lighting modification made during Yr 2 not only emulated natural changes in sunrise and sunset, but also daily intensity variations that may play a role in triggering reproductive events. In addition to manipulating environmental cues, we administered exogenous hormones. At present, the two most common hormones used to promote amphibian captive breeding efforts are LHRH and hCG (Roth and Obringer 2002; Browne and Zippel 2007; Kouba et al. 2009). Significant species differences exist in regard to hormone use for gamete production in amphibians (Roth and Obringer 2002; Browne and Zippel 2007; Kouba et al. 2009). We administered LHRH at dosages (extrapolated per ug/g body weight) similar to those used to induce spermiation and ovulation in anurans (Waggener and Carroll 1998; Obringer et al. 2000; Browne and Zippel 2007; Kouba et al. 2009). Intraperitoneal injection of hormone was achieved by the use of anesthetic. We used MS222 at a concentration (0.05%, Fellers et al. 1994) lower than that used for anesthesia of terrestrial salamanders (Wright 2001), but similar to what has been reported in larval (Gentz 2007) and paedomorphic salamanders (Crook and Whiteman 2006; Mansour et al. 2011). Induction was fast and recovery was noted by the conscious control of gills along with the ability to swim and mobilize limbs. Anesthetic events in *N. beyeri* did not appear to interfere with subsequent reproductive behaviors of spermatophore deposition, ovulation, oviposition, and egg brooding.

To help stimulate spermatophore deposition during the breeding season, the male *N. beyeri* was treated with LHRH between December and March. Dosage remained the same over the two years of treatment. During the first year, we tested the ability of the male to respond at the end of the breeding season and were unsuccessful in obtaining spermatophores. In Yr 2, the male was treated with LHRH in early December and we did not see evidence of spermatophore deposition until 27 days post-injection. While axolotls treated with Ovopel or hCG release spermatophores 36–40 h post-injection, researchers could manually collect sperm > 10 hr after injection (Mansour et al. 2011). Similarly, wild caught *N. maculosus* treated during the breeding season with whole sheep pituitaries deposited spermatophores within 1–2 days (Bishop 1932). It is possible that the male *N. beyeri* deposited spermatophores in similar time to the aforementioned studies and were just not observed.

The spermatophore and spermatozoa of *N. beyeri* were similar to those described for *N. maculosus* (Bishop 1932; Baker 1963). Microscopic examination of the spermatophore revealed no motility of individual sperm. Studies have reported motility of *Necturus* sperm when harvested from the testes, sperm duct, and cloaca (Baker 1963; Shoop 1965). We are not aware of any report regarding sperm motility in naturally occurring spermatophores of *Necturus*. It remains unknown if substances in the spermatophore inhibit/retard sperm motility upon deposition. It has been shown that sperm are inactive during storage in the spermathecae (Hardy and Dent 1986). Although motility was not detected in the one spermatophore examined, fertile spermatophores were deposited as viable offspring were produced by both *N. beyeri* females. Even if sperm storage occurred beyond the predicted 6 months (Sever

and Bart 1996), parentage would not change as the same male was housed with both females over the 2.5-Yr period.

Despite warming of water temperatures and lengthening daylight, ovulation and oviposition did not occur in Yr 1. Mature unovulated eggs likely underwent degeneration (Kessel and Panje 1968). Exogenous administration of LHRH occurred in one female during Yr 2 to promote ovulation and oviposition. The male was removed from the tank following hormone treatment, as males and females appear to segregate during egg laying *in situ* (Eycleshymer 1906). Ultrasonography was found to be a useful tool in diagnosing gravid status in *N. beyeri*. Egg measurements were similar to what has been reported for *Necturus in situ* (Shoop 1965). *Necturus* exhibit high synchronicity in egg deposition in the wild (Smith 1911), and this is what we observed *ex situ*. Likewise, egg deposition occurred over the span of many hours to days (Eycleshymer 1906). The *N. beyeri* female deposited eggs 72–96 h after LHRH, a bit longer than the 36–48 h noted for female axolotls treated with Ovopel or hCG (Mansour et al. 2011). Because the untreated female *N. beyeri* also deposited eggs and did so prior to the treated female, we cannot conclude hormone treatment was responsible for egg deposition. Time from oviposition to hatching was slightly longer than what has been reported for *N. beyeri* nests obtained *ex situ* and subsequently raised to hatching *in situ* (Shoop 1965). Prior to our study, attempts to artificially brood *Necturus* eggs were limited (Shoop 1965). It is hypothesized that female *Necturus* aerate eggs by rapid gill movement and this movement helps destroy fungal hyphae (Salthe and Mecham 1974). We observed greater levels of egg loss from the nest of the female that deposited eggs on wood versus stone surfaces. For reasons unknown, females may cannibalize their own clutch (Salthe and Mecham 1974). While we did not find this to be the case, females did cannibalize conspecific nests and had to be isolated from the remainder of developing eggs. Interestingly, it did appear as if females were able to detect nonviable eggs/embryos within their own clutch. Of the six *N. beyeri* embryos that successfully hatched, none exhibited any abnormalities (Shoop 1965).

Acknowledgments.— This work was financially supported by the Association of Zoos and Aquariums Conservation Endowment Fund and the Disney Worldwide Conservation Fund. Additionally, support was received through a private donation from Ms. Iris de la Motte. We acknowledge Erik Keyster and John Staubach, Cincinnati Zoo & Botanical Garden, for their significant contributions to the project.

HERPETOCULTURE NOTES

SQUAMATA — SNAKES

***CARPHOPHIS AMOENUS AMOENUS* (Eastern Wormsnake). LONGEVITY.** *Carphophis a. amoenus* is a small, secretive, semi-fossorial colubrid snake occurring in much of eastern North America (Ernst et al. 2003. Cat. Amer. Amphib. Rept. 774:1–7). Possibly because of this species' burrowing and secretive habits, it is rarely maintained in captivity (Rossi 1992. Snakes of the United States and Canada: Keeping them Healthy in Captivity, Vol. 1, Krieger Publishing Co., Malabar, Florida. i–xiv + 209 pp.). Snider and Bowler (1992. Longevity of Reptiles and Amphibians in North American Collections. SSAR Herpetol. Circ. 21:1–40) reported the captive longevity record for a wild-caught adult to be 1 year 1 month and 10 days.

On 1 May 2005, I acquired a wild-caught adult male *C. a. amoenus* (240 mm+ TL; missing tail tip). The snake was housed and fed as reported by Gray (2007. NC Herpetol. Soc. Newsltr. 30[2]:15).

On 13 March 2014, the *C. a. amoenus* was found dead in its enclosure after 8 years 10 months and 12 days in captivity, greatly exceeding the previous captive longevity record for this species. At the time of its death the snake had attained a snout–vent length of 245 mm and 278 mm TL. This *C. a. amoenus* was maintained under permit no. 15-07 issued by the Pennsylvania Fish and Boat Commission. The specimen was deposited in the reptile collection of the Natural History Museum at the Tom Ridge Environmental Center (TREC – 00107).

Thanks to Jeff Beane for reviewing this manuscript.

Best Practices in Herpetological Taxonomy: Errata and Addenda

In a recent issue of *Herpetological Review*, my co-authors and I published a *Point of View* article outlining a set of best practices for workers in the field of herpetological taxonomy (Kaiser et al. 2013). The goal of that article was to defend modern herpetology from "taxonomic vandalism" (see Jäch 2007), and it has generated considerable discussion among zoological taxonomists (e.g., in the online listserv *Taxacom*). There is broad, although not unanimous, agreement on the part of herpetologists with our proposed solutions for how to handle taxonomic vandalism, and there is widespread recognition amongst zoological taxonomists in general that (1) taxonomic vandalism in zoology occurs and can pose a problem for users, (2) that the *International Code of Zoological Nomenclature* (ICZN 1999; hereafter, the *Code*) in its function as an accounting system outside of the scientific method cannot safeguard scientific output from interference by authors who do not conform to scientific principles (see Kaiser 2013), and (3) that the adjudication of taxonomic decisions ultimately remains in the hands of authors, editors, and, in terms of the resulting nomenclature but not the taxonomic decisions, the International Commission on Zoological Nomenclature (hereafter, ICZN). I am pleased to report that authors (e.g., Bates et al. 2013; Reynolds et al. 2014) as well as editors (e.g., Measey 2013) are now applying the recommendations we made. It is the purpose of this follow-up paper to correct four minor errors made in the earlier paper's list of taxonomic recommendations (Kaiser et al. 2013: Table 1), augment that list with a new set of recommendations for 255 unscientific names presented by Hoser (2013a–ag[1]), and provide some clarification of the earlier paper regarding the relationship between scientific taxonomy and the *Code*.

Errata

Recommendation for Costinisauria couperi *Wells 2009*.—Kaiser et al. (2013) erroneously recommended the use of *Lampropholis couperi* in place of *Costinisauria couperi*. Instead, they should have listed *Eulamprus kosciuskoi* as the correct recommendation. The original listing of *C. couperi* in Wells (2009) shows that the author intended to separate his purported species from *C. worrelli* Wells and Wellington 1985, a name in the synonymy of *E. kosciuskoi* (see Shea and Sadlier 1999).

Recommendation for Cyrtodactylus abrae *Wells 2002*.—Kaiser et al. (2013) erroneously recommended the use of *Cyrtodactylus tuberculatus* in place of *C. abrae*. Instead, they should have listed *C. pulchellus* as the correct recommendation. The authors overlooked an important recent paper, in which Shea et al. (2011) investigated the status of *C. abrae*. By designating the lectotype of *C. pulchellus* as the neotype of *C. abrae* (a poorly described taxon based on a photograph, and for which the nominal holotype did not exist), Shea et al. (2011) permanently relegated the name *C. abrae* to the status of junior synonym of *C. pulchellus*.

Recommendation for Zeusius sternfeldi *Wells 2007*.—Kaiser et al. (2013) erroneously recommended the use of *Cyclodomorphus casuarinae* in place of *Zeusius sternfeldi*. *Zeusius sternfeldi* is, in fact, a synonym of *C. venustus*. In his description of *Z. sternfeldi* Wells (2007) listed, without attribution, diagnostic characters from Shea and Miller (1995) for a population these authors considered conspecific with *C. venustus*.

Typographical error.—In Table 1, Kaiser et al. (2013) list the name Calloselasma, without italic lettering, as a new tribe presented by Hoser (2012b). This name should have been listed as Calloselasmiini. Hoser (2013m) described this putative tribe as new for the second time, both times in violation of the Principle of Coordination (Article 36 of the *Code*).

Addenda

In the course of writing the recent *Point of View* paper, my co-authors and I fully anticipated the production of additional taxon names by Raymond Hoser, but we were nevertheless dumbfounded by the sheer number of new names he created in five recent issues of his self-published *Australasian Journal of Herpetology* (hereafter *AJH*). In these issues, Hoser proposes a globe-spanning series of 255 new names for snakes and turtles at the family, subfamily, tribe, subtribe, genus, subgenus, species, and subspecies level. Following the standard of Kaiser et al. (2013), I here list these new names with recommendations for scientifically valid names (Table 1). In this list I also identify taxa violating Article 29 (proper formation of family-group names) and Article 36 (Principle of Coordination) of the *Code* and present corrections. I wish to note that, contrary to the exclamations by Hoser (2013n), the recommendations by Kaiser et al. (2013), and the ones presented herein are not formal taxonomic decisions underpinned by new evidence, but simply the most appropriate names to be used in place of dubious taxon names presented by Hoser since the year 2000; I consider Hoser's post-2000 names non-existent for the purposes of taxonomy and nomenclature. The names coined by Hoser (2003), inadvertently omitted by Kaiser et al. (2013), are included in this new listing.

Best Practices Revisited and Reaffirmed

There are two fundamental issues when dealing with non-peer-reviewed, unscientific contributions in taxonomy. The first of these is to clearly define the line separating taxonomy and nomenclature, as defined and differentiated by Pyle and Michel

[1] As for the year 2012 (see Kaiser et al. 2013), due to the large number of works produced by Raymond Hoser in 2013 (N = 33), I continued the enumeration of citations by beginning the alphabet anew. Thus, in addition to Hoser (2013a–z), nine additional references exist (Hoser 2013aa–ai).

TABLE 1. List of 255 herpetofaunal taxa published as new by Raymond Hoser from April–September 2013, plus one set of names from Hoser (2003) that was inadvertently omitted by Kaiser et al. (2013). I follow Kaiser et al. (2013) in considering the manner in which these names were produced unscientific, in violation of Articles 8.1.1, 29, 36 and the *Code of Ethics* of the *International Code of Zoological Nomenclature* (ICZN 1999); these dubious names therefore have no standing in taxonomy and nomenclature. Readers *should not use these names* but instead revert to those listed in the column titled "Recommendation," where nomenclaturally available and taxonomically suitable scientific names are provided. For clarification, the Recommendation column shows subgenera in parentheses with their corresponding genus name, according to standard nomenclatural usage. The Recommendation column may include several scientifically valid names when a nonscientific higher group taxon (e.g., tribe, subtribe) encompasses multiple lower ranked taxa. All other capitalized and italicized names are genera or subgenera. These recommendations do not constitute synonymies under the rules of the *Code*, but serve as substitutes for Hoser's names until a formal, scientific treatment for the groups under consideration is published. A name formed incorrectly according to Article 29 of the *Code* is identified by the superscript A29. A name, whose description as new violates the Principle of Coordination of the *Code* (Article 36) and therefore is not new, is identified by the superscript A36. In these cases, a corrected version of the name and/or the proper authorship is provided after the taxon name. The footnotes list a variety of incongruities, including some with formal relevance.

[1] Fig. 4 in Vidal and Hedges (2009) shows that Malagasy boine snakes are part of an unresolved polytomy.
[2] Hoser (2013ad) includes in this group the species *Hypsilurus spinipes* and the genus *Tiaris* Duméril and Bibron 1837 (now known as *H. dilophus*). In the original description of their species *Lophyrus dilophus*, Duméril and Bibron (1837:421) list in their observation section that the name "*Tiare dilophe*" applies to the specimen figured on Plate 46 of their *Atlas*. There, it is denoted as *Tiaris dilophus*. However, the genus name *Tiaris* Duméril and Bibron 1837 was preoccupied by the genus *Tiaris* Swainson 1827, a taxon erected for a genus of songbirds in the tanager family (Thraupidae). The use of this genus in the definition of a tribe is incorrect.
[3] The taxon listed here was previously described by Hoser (2012b) and rejected by Kaiser et al. (2013).
[4] The taxon was also described as *Antaresia maculosus brentonoloughlini* by Hoser (2004) and rejected by Kaiser et al. (2013).
[5] The definition of this subgenus by Hoser (2013o) is confusing because of poor grammar, and no species content is formally presented. While the author states that the type species for the subgenus is *Bitis parviocula*, the later text appears to confound the subgenera *Macrocerastes* and "*Kuekus*."
[6] The entire first paragraph of the putative diagnosis for *Bothrops* "*mexicoiensis*" is a verbatim copy of the diagnosis for *B.* "*lenhoseri*." This is also the case for the diagnosis of *B. m.* "*maccartneyi*." Furthermore, to indicate a Mexican origin, the proper form for the name would be *mexicoensis*. To create a patronym for an individual with last name McCartney, as stated in the etymology, the proper form is *mccartneyi*.
[7] The subspecies of *Malayopython reticulatus* listed here were previously described by Hoser (2004) and rejected by Kaiser et al. (2013).
[8] According to Vidal and Hedges (2009:Fig. 4), "the phylogenetic position of the Pacific Island endemic genus *Candoia* remains uncertain."
[9] This taxon was previously described by Hoser (2012b), without the lapsus in spelling. It was rejected by Kaiser et al. (2013).
[10] The taxon listed here was already described by Hoser (2012d) and rejected by Kaiser et al. (2013).
[11] Also described as *Chondropython viridis shireenae* by Hoser (2004) and rejected by Kaiser et al. (2013).
[12] Given that the name derives from an individual named George Konstandinou, a proper spelling for such a group would be *Georgekonstandinous*.
[13] This is the second description of a species named *Gerrhopilus carolinehoserae*. The first was by Hoser (2012a), which was rejected by Kaiser et al. (2013).
[14] Given that the name derives from an individual named Lachlan McConchie, a proper spelling for such a group would be *mcconchiei*.
[15] The taxon listed here was already described by Hoser (2012c) and rejected by Kaiser et al. (2013).
[16] Also described as *Katrinus fuscus jackyae* by Hoser (2004) and rejected by Kaiser et al. (2013).
[17] A proper name indicating a Bornean origin would be *borneensis*.
[18] A proper name indicating Philippine origin would be *philippinensis*.
[19] The name Macrochelidae is preoccupied by a group of mites.
[20] Also described by Hoser (2004) and rejected by Kaiser et al. (2013).
[21] Hoser (2013ac) lists this as "Subtribe Tracheloptychina trib. nov." The subtribe ending -ina conflicts with the designation of this name as a tribe.
[22] Hoser (2013ac) lists this as "Subtribe Zonosaurina trib. nov." The subtribe ending -ina conflicts with the designation of this name as a tribe.

(2008), to determine which aspects of a body of work are in the purview of science and which are not. Taxonomy is based on data and argument (a scientific process), and if a disagreement occurs over evidence or its interpretation, then alternative taxonomies may coexist. Nomenclature, in contrast, is a system of rules based on general principles, through which the application of taxon names is regulated. It is not based on science, but for the system to be meaningful *there must be sound scientific principles underlying the creation of any new taxon name*. Thus, the workflow for proposing new taxon names automatically and invariably involves first science, using an explicit and transparent scientific process (i.e., a peer-reviewed publication), and then accounting, with all subsequent information regarding the status of a taxon name derived from accounting (Kaiser 2013). While it is true that the *Code* applies only to nomenclature, given its overall presentation (including its *Preamble, Introduction,* and *Code of Ethics*), it seems reasonable to assume that reliable scientific processes ought to underlie nomenclature.

The *Code* states that its application will be subservient to the "promotion of stability and universality in the scientific names of animals" (*Preamble* of the *Code*; ICZN, 1999). I interpret this as an attempt by the original authors of the *Code* to ascertain that scientific processes must govern the interactions between taxonomy and the *Code*. In my opinion, that is how Article 8.1.1 must be understood. If it can be shown that scientific principles are violated (i.e., data and argument for the specific case are not merely poorly interpreted, but missing, erroneously or deliberately misrepresented, or entirely outside of acceptable scientific principles), then the taxonomy and names produced by such means are unscientific. Names produced in this manner should therefore be considered nomenclaturally void, and should neither be permitted to receive approval via the *Code*, nor be able to subsequently re-enter the realm of science after having been "laundered" by the *Code* (Kaiser 2013).

The best practices presented by Kaiser et al. (2013) were designed to help taxonomic herpetologists and users of herpetological taxonomy recognize and sort post-2000 taxon names, and the publications in which they appeared, into acceptable and unacceptable columns. These recommendations are universally applicable: a user can take any article and check it against the listed criteria, then make a determination regarding the validity of any taxonomic decision it might contain. Using this approach, Kaiser et al. (2013) were able to declare the post-2000 output by the Australian snake aficionado Raymond Hoser void for nomenclatural purposes and provided a corresponding list of taxon names with nomenclatural validity. The particular issue with Hoser's output is not only the proposal of taxonomically unfounded and superfluous reptile names (more than 200 in 2013 alone; Hoser 2013a–ag), it includes attacks on professional and non-academic herpetologists who disagree with Hoser's concept of taxonomy, something I perceive to consist of little more than a competitive naming game to him. Following the publication of Kaiser et al. (2013) in March of 2013, Hoser worked the online social media circuit to discredit the authors and supporters of that paper, along with the journal and its editor, as well as the scientific societies that voted in support of the presented ideas (e.g., Hoser 2013n). His deportment is in clear violation of the *Code of Ethics* of the *Code*, as has frequently been stated in online venues. This is perhaps most significantly demonstrated by an exchange between Hoser and ICZN Commissioner Douglas Yanega in the listserv *Taxacom* (Hoser 2013ah). These exchanges are the source of gross misinformation about the relevant issues and scientific processes, and they have caused significant discontentment among taxonomists.

A key issue emerging in this discussion is the position of the *Code* and the ICZN. At their root, the rules and their governing body provide zoological taxonomists with a mechanism for the accounting of taxon names and for resolving disputes arising from the publication of available names. Alas, this mechanism is by design not scientific, and it is perhaps better likened to a system of legal oversight (Kaiser 2013). These entities were not established to influence the scientific processes by which taxonomic decisions are made. While this has fostered the independence of two important regulatory aspects of taxonomy, it has also created a problem: although the nonscientific component is strictly governed, the scientific one is not. I therefore feel I must preface the discussion of the *Code*'s specifics by stating that I am a firm proponent of the scientific process, a grand, yet imperfect human endeavor by which we produce knowledge. If the *Code*, a tool created by scientists for use by scientists to sort out nomenclature, does not unequivocally support this scientific process (which is the ultimate reason for the *Code*'s very existence), then the *Code* becomes irrelevant to science. While the *Code* provides a very valuable service, its application must always be congruent with scientific principles, and not for the protection of the *Code* in and of itself. The *Code* has adapted (e.g., ICZN 2012), and must continue to adapt, to the realities and demands of modern science, and it must do so as the situation demands it (see Harvey and Yanega 2013). The broader issue, therefore, is the use of the scientific method for creating knowledge, and the relevance of the *Code* to that goal.

Article 8.1.1 of the *Code* exemplifies how working within the framework of the *Code* and the ICZN creates challenges for those contending with names produced by taxonomic vandals. This article states that for a work to be considered published for the purposes of zoological nomenclature, "it must be issued for the purpose of providing a public and permanent scientific record" (ICZN 1999). Kaiser et al. (2013) and Schleip (2014) discuss this article in relation to Hoser's output in the *AJH*. Based on the online discussions that have followed (e.g., on *Facebook* pages and in *Taxacom*), as well as the presentation of *AJH* issues 16–18, it is instructive to revisit the ramifications of this article.

On the surface, glossy presentation and overall production of pseudoscientific[2] materials, such as the *AJH*, may closely mimic a scientific journal and can lead to confusion on the part of users, particularly in an applied setting where taxonomic minutiae may not be verified (e.g., Wüster and Bernils 2011). On the back pages of the two most recent issues of the *AJH*, it is even stated that articles are published "in a peer reviewed journal for permenant public scientific record" (grammar and spelling as in original). However, presentation and proclamation alone do not a scientific journal make. Even statements touting compliance with scientific rules cannot compensate for a lack of rigor in data presentation. For example, Hoser states multiple times in each issue of the *AJH* that his articles are designed to be "in accordance with the Zoological Code" (e.g., Hoser 2013ac:18), yet they fail scientific principles in even the most basic aspects

[2] Pseudoscience is an attempt to clothe nonscientific fact in scientific attire to validate fictional, non-reproducible information. Pseudoscience does not pose a question and seek an explanation; it begins with the explanation and then seeks supportive data. Pseudoscientific statements are generally easy to recognize by the vocal defense that typically accompanies their presentation, unlike science, where the evidence can speak for itself. In contrast to science, there is no knowledge gained through pseudoscience.

of reproducibility and data disclosure. While Hoser indeed works hard to make the *AJH* a public and permanent record, it is the term "scientific" where he fails the test of Article 8.1.1. In light of this, it is highly questionable whether the *AJH*, in the absence of the *Code*, would ever obtain permanence in the Scientific Record (see Dayrat 2005; Minelli 2005).

Following the best practices of Kaiser et al. (2013), the contents of the *AJH* are clearly noncompliant with broadly accepted scientific standards. From an administrative or oversight perspective, both an editorial board and associate editors are lacking. Hoser's role as the only contributor creates a conflict of interest for the peer-review process given his role as the *AJH*'s Editor. In terms of editorial quality, a reading of any article in the *AJH* demonstrates that there is no peer review despite Hoser's attestations to the contrary: no person upholding scientific principles and standards of collegial discourse (not to mention familiarity with English grammar, paragraph structure, or scientific writing) would accept *AJH* contributions (Carraway 2009). A scientific journal is not created by proclamation, but by the consistent production of quality, demonstrably peer-reviewed scientific output.

Regarding the taxonomic details of the articles in *AJH* issues 16–21, Hoser provides ample evidence that the names he proposes are not based on the scientific study of specimens or offered out of scientific necessity, which violates the scientific tenets of taxonomy and eliminates the utility of any resulting names. The main interest of Hoser is to have his proposed names endure, with the help of the *Code*. They are not the products of the scientific process, but generated "for completeness" (e.g., Hoser 2013a:3), which results in names for ranks that are not informative or useful. Indeed, most appear to be named for the sake of naming them: (1) naming clades for which molecular data from peer-reviewed publications may be preliminary or provide weak support, (2) names proposed from holotypes and paratypes that Hoser designates, yet has never examined himself, or (3) listing long strings of in-text citations rather than critically reviewing the relevant data from such papers (invariably ending with the phrase "and sources cited therein;" this occurs 38 times in the 33 papers comprising *AJH* issues 16–21). Hoser even states periodically that he does not want to rehash prior work (e.g., Hoser 2013a:4, 2013z:34, 2013ae:38), even when such work would support his taxonomic proposals.

Some may consider it impossible to differentiate scientific from nonscientific works so that it can be objectively determined which taxonomic decisions should have nomenclatural impact. I disagree. Based on the fundamental processes of science accepted today, developed and refined over centuries, it is a simple task to separate poorly executed science from pseudoscience. These are not matters of free speech or freedom of expression, which in science are restricted by evidence (Kaiser 2013). If it is not science, then it shall not be known as such. This has been amply and successfully demonstrated as evolutionary science defended itself against Intelligent Design, and it is certainly possible and appropriate in applications to taxonomy. This is not just a question of publishing outlet, but more specifically a question of whether basic scientific principles are followed or not.

Perhaps Hoser's most recent output is *Code*-compliant when it comes to the "public" or "permanent" aspects of Article 8.1.1. After all, the issues of the *AJH* are bound, available for purchase, and are distributed to some public libraries. But the output is by no measure "scientific" and clearly in violation of Appendix A of the *Code* (the *Code of Ethics*).

I have encountered the argument that Hoser's output merely represents exceptionally poor taxonomy, like that of some taxonomic vandals outside of herpetology, but with the addition of the many slanderous interpersonal transgressions and name-calling, and that over time scientists will correct the record. However, Hoser's prolific output, which as of this writing includes well over 600 new taxon names since 2000 (the exact number would require close scrutiny because the author tends to describe taxa as new more than once, and he calls higher taxon names "new" even when their authorship was already established according to Article 36 of the *Code*), creates significant instability for users of taxonomy in the herpetological community. Thus, the *Code*, whose explicit mandate includes the oversight of stability of scientific zoological nomenclature, is being co-opted by Hoser as a tool to create confusion in herpetological taxonomy[3]. The issue of taxonomic vandalism therefore is not merely a matter of working within the *Code* and exploiting its loopholes; it amounts to an example of treasonous conduct in the framework of zoological science.

A significant segment of the herpetological community is on record as rejecting the post-2000 names coined by Hoser (Kaiser et al. 2013), and given that these recommendations are being implemented in recent papers (e.g., Bates et al. 2013; Reynolds et al. 2014; Schleip 2014) and by editors (e.g., Measey 2013), this is likely to become the *status quo* for reptile taxonomy: science forges ahead as nonscience is overwritten. Despite this trend, the position of the *Code* and the ICZN vis-à-vis Hoser's nomenclature remains unresolved. Those interested in this issue can comment on Case 3601 filed by Hoser (2013ai) to preserve the genus name *Spracklandus* Hoser 2009 (published in the *AJH*) over *Afronaja* Wallach et al. 2009 (published in *Zootaxa*). This could prove to be a landmark case insofar as it pits the value of the scientific process against pseudoscience in nomenclature (Kaiser 2013, 2014).

I assert that one of the best options to resolve the issue of taxonomic vandalism in general, and of the situation described herein in particular, is for the ICZN to use its plenary powers under the *Code* to declare names proposed by Raymond Hoser unavailable for the purposes of nomenclature (Kaiser 2013). To resolve the problem in herpetology, it would suffice to do so with names proposed in the *AJH*, because that is where the most egregious offenses against scientific taxonomy have occurred. While this would not prevent Hoser from launching another outlet, it would set the precedent that the ICZN will not stand by as the system it safeguards is subverted and compromised.

Acknowledgments.—I thank G. Shea for his many insightful and helpful comments on the manuscript and for clarifying the status of the three lizard species for which Kaiser et al. (2013) made incorrect recommendations. I am also very grateful to S. Nikolaeva for her help in clarifying the issues relating to Articles 29 and 36 of the *Code*. I thank A. Koch, M. O'Shea, W. Schleip, V. Wallach, and W. Wüster for their assistance in streamlining my ideas and for checking the recommendations in Table 1.

Note to the reader: In the following list, publications by Raymond Hoser have all errors in punctuation or spelling preserved.

[3] The most recent example for such confusion is listed in the newest edition of *Reptiles and Amphibians of Australia* (Cogger 2014). The author highlights in the account for the genus *Silvascincus* that readers will likely encounter two names for these lizards, of which the earlier name was rejected by Kaiser et al. (2013); in the account, the older name is nevertheless only listed second and in parentheses.

The Bold Taxonomic Hypotheses of Collins (1991): 23 Years Later

> "**Bold ideas,** unjustified anticipations, and speculative thought, are our only means for interpreting nature: our only organon, our only instrument, for grasping her. And we must hazard them to win our prize. Those among us who are unwilling to expose their ideas to the hazard of refutation do not take part in the scientific game." Popper (1959:280).

BRIAN I. CROTHER
Department of Biological Sciences, Southeastern Louisiana University, Hammond, Louisiana 70402, USA
e-mail: bcrother@selu.edu

In the pages of this journal in 1991, Joseph T. Collins published a set of bold hypotheses under an innocuous sounding title: "Viewpoint: A new taxonomic arrangement for some North American amphibians and reptiles." This paper proposed 55 hypotheses about species. Specifically, Collins proposed the elevation of 55 nominal subspecies to species based on the application of the evolutionary species concept (ESC). As defined by Wiley (1978:18), evolutionary species are "... a single lineage of ancestral descendant populations of organisms which maintains its identity from other such lineages and which has its own evolutionary tendencies and historical fate." Wiley (1978:18–19) was quite explicit with regard to the development of

hypotheses based on his definition, "The definition is empirical in that it permits hypotheses from which can be tested…For example, we may frame the hypothesis, 'these two populations (or groups of populations) maintain separate identifiable evolutionary lineages.' Evidence used to test such an hypothesis can come from a variety of sources depending on the nature of the organism and the genetic, phenetic, spatial, temporal, ecological, biochemical and/or behavioral evidence which is available to test the question. *Whether a group of organisms is or is not a species then becomes an hypothesis to be tested*" (emphasis added). In many ways, the above quote forms the foundation of this retrospective of Collins' (1991) proposals.

The year before, Frost and Hillis (1990) published an influential paper on the ESC and its application in herpetology. One of the conclusions that Frost and Hillis (1990:93) reached, and certainly the most relevant for Collins, was that "where allopatric populations have not been demonstrated to be parts of a monophyletic group of very similar populations (e.g., *Bufo m. microscaphus* and *B. m. californicus*), we consider them to be distinct evolutionary species and name them as binomials (i.e., *B. microscaphus* and *B. californicus*)." Frost and Hillis (1990) gave numerous other examples where allopatric populations had been investigated and found to be multiple species, which led them to predict (p. 94), "... most of the large 'polytypic' species left (such as *Ambystoma tigrinum, Necturus maculosus, Sceloporus jarrovii, S. undulatus, Diadophis punctatus, Pituophis melanoleucas, Lampropeltis getula, Tantilla rubra, Thamnophis sirtalis*, and *Crotalus durissus*) will be found to be composed of several evolutionary species." The claims of Frost and Hillis (1991) at that time were bold, and presumably emboldened Collins.

Applying the arguments of Frost and Hillis (1991; which were an extension of Wiley [1978]), Collins (1991:43) made the philosophical and operational leap to treat allopatric North American amphibian and reptile subspecies as species as lineages: "the following taxa exhibit two characteristics which reveal their specific distinctiveness: 1) They are mapped as allopatric (based on the best published evidence available), and 2) they are in some way morphologically (and presumably genetically) distinct." Of course, like all change, this leap was controversial and did not go unchallenged. Three response papers (Lazell 1992; Montanucci 1992; Van Devender et al. 1992) appeared in *Herpetological Review* that argued strongly against Collins's hypotheses (for many reasons) and these rebuttals were in turn answered (Collins 1992; Frost et al. 1992). The debates were lively and enlightening and led to an awakened interest in the nature of species among herpetologists.

My purpose here is not to rehash the debates and the battles already fought and, frankly, won by proponents of the ESC, but instead to ask the empirical question: How many of Collins' hypotheses have been falsified? In my opinion, answering this question should be an important addition to the debates. Was Collins' trust in the ESC justified? Were the theory and philosophy behind the ESC well-founded? If the predictions of Collins were not rejected, then the answers to these questions should be "yes."

To address the question of how many of Collins' 1991 hypotheses have been falsified, I took the list from Collins (1991) and reviewed the systematics literature for each species. Based on the literature since 1991 (with a couple exceptions), the hypotheses were designated as either (1) failed to falsify, (2) failed to falsify but different from proposed, (3) falsified, and (4) unstudied. Failed to falsify means the hypothesis of Collins (1991) was corroborated as originally proposed. Failed to falsify but different means that although Collins (1991) was correct in proposing multiple species present, the discovered patterns were different, and more complicated than he predicted. Falsified hypotheses mean that the allopatric subspecies were found to be part of a single species. Unstudied hypotheses are precisely that; no work has been done to address what Collins proposed.

Of the 55 subspecies-to-species elevations proposed by Collins (1991), 40 (73%) had been studied by other investigators as of March 2014. Of those 40, 23 of Collins's hypotheses were corroborated (or were not rejected), six others had more complicated patterns of species distributions than predicted, and 11 were falsified (Table 1). Several of the decisions were not straightforward; it was not my intention to reinterpret the work of others, but simply to tally results. Some had actually been proposed as species prior to the publication of Collins's (1991) viewpoint. For example, Packard (1971) argued that regardless of reproductive compatibility, the disjunct population of *Anaxyrus* [then *Bufo*] *hemiophrys* recognized as *A. h. baxteri* was evolving independently of *A. h. hemiophrys* and should be recognized as a distinct species. Recognition of *A. baxteri* was supported later by Smith et al. (1998). *Thamnophis couchii gigas* is a similar case, where Rossman and Stewart (1987) previously had shown *T. gigas* to be a diagnosable lineage separate from *T. couchii*. These cases were included in the tally simply because Collins (1991) included them.

Is there any meaning that can be ascribed to only 11 hypotheses (out of the 40 tested) being falsified? Yes. Collins (1991) is an important paper because it challenged all of us to deal with the practical application of evolutionary science to taxonomy. Collins (1991) also strongly promoted further discussion on the nature of subspecies and their importance/relevance in understanding biodiversity. As circumstantial evidence, consider that from 1956 to 1990 (34 years), the number of subspecies recognized in nominal species of reptiles and amphibians in the USA dropped by 61, but from 1990 to 2012 (22 years), the number of subspecies dropped by 165 (Collins 1990; Conant et al. 1956; Crother 2012). Was this dramatic decline in the number of recognized subspecies caused by Collins (1991)? As noted above, Collins' (1991) polarizing paper was an empirical extension of the arguments of Frost and Hillis (1990), and coincident with the rise of molecular phylogenetics (e.g., Hillis and Moritz 1990), which provided new data and tools that spurred on phylogenetic research of North American amphibians and reptiles. While it can be argued that the philosophical and methodological advancements played a more important role in the decline of recognized subspecies, if Collins (1991) did not contribute to that decline, he certainly saw it coming (Collins 1991:42): "Besides providing recognition of the real species diversity in nature, a rigorous application of the evolutionary species concept (as discussed in Frost and Hillis 1990) would also reduce the number of arbitrarily defined subspecies dramatically…"

Collins (1991) exposed the false worry that nomenclatural instability may lead to chaos (see Pauly et al. [2009], Crother [2009], and Frost et al. [2009] for a recent debate of this issue); this "chaos" actually reflects the shock of change within the taxonomic community (Hedges 2013). Rarely considered, but of significance nonetheless, the results of the tests of Collins' hypotheses reflect the seeming fact that geographic disjunction, both allopatric and peripatric, are important drivers of speciation (Mayr [1963] was arguably the key work that solidified this orthodoxy). In the same vein, the results also supported a prediction of the ESC (Frost and

TABLE 1. Status of subspecies elevated by Collins (1991). 1 = Failed to falsify, 2 = multiple lineages but different than hypothesized, 3 = falsified, 4 = unstudied. See text for further explanation.* = determined there was not enough evidence to support or reject (C. Austin, pers. comm.).

Hillis 1990; Frost and Kluge 1994; Wiley 1978): if two populations are disjunct, and diagnostically distinct, the evidence suggests that they are on independent evolutionary trajectories and thus are species. And finally, Collins (1991) implicitly embraced Popperian (Popper 1959, 1962, 1972, 1983) logic by not waiting for the slow accumulation of inductive statements before proposing his hypotheses, but instead was bold in his proposals and risked the "hazard of refutation" (Popper 1959:280) with his hypotheses.

Although many of Collins's predictions were correct, this kind of taxonomy is not encouraged. I do not advocate nomenclatural changes that are not based on data (see Kaiser et al. 2013). However, it would advance our knowledge of biodiversity if biologists were less reticent about naming discovered lineages they identify in their phylogenies. After all, the phylogenetic system was originally developed for the specific purpose of classification (Hennig 1966; Wiley 1980).

Acknowledgments.—I thank T. Taggart for the invitation to speak at the Kansas Herpetology Society meetings in 2012, for which this paper was developed and presented. C. Beachy, C. Fontenot, D. Frost, D. Sever, and M. White kindly read and commented on the manuscript. I am grateful to C. Austin, J. Boundy, F. Burbrink, and S. Ruane for answering my inquiries and M. McCallum for sharing citations. I also thank two anonymous reviewers for noting an unintended message in an earlier draft.

***AMPHIUMA MEANS* (Two-toed Amphiuma)**. USA: ALABAMA: Chilton Co.: 0.40 road miles SE of AL 22 on AL 6, beaver pond just west of highway (32.76174°N, 86.87677°W; WGS84/NAD83). 13 April 2013. C. Davis. AUM 40194. Verified by David Laurencio. New county record (Mount 1996. The Reptiles and Amphibians of Alabama. University of Alabama Press. xi+347 pp.). Caught with baited funnel trap.

Dallas Co.: 0.34 miles WSW of AL 14 along train tracks (32.42926°N, 86.95938°W; WGS84/NAD83). 30 June 2013. C. Davis. AUM 40282. Verified by David Laurencio. New county record (Mount 1996, *op. cit.*). Caught with baited funnel trap,

A. means is assumed to occur throughout the lower half of the state; however, verified records are lacking for many Alabama counties.

CHRIS W. DAVIS, (e-mail: cdavis53@aum.edu), **CHELSEA K. WARD**, and **JOHN M. AHO,** Auburn University, Montgomery, Alabama 36124-4023, *USA;* **ROGER D. BIRKHEAD**, Alabama Science In Motion, Auburn University, Alabama 36849-5414, USA (e-mail: birkhrd@auburn.edu).

***BATRACHOSEPS CAMPI* (Inyo Mountains Salamander)**. USA: CALIFORNIA: Inyo Co.: southwestern Inyo Mountains, an

unnamed canyon between Fossil Hill to the north and Union Wash to the south (36.72°N, 118.02°W; WGS84). 9 June 2013. Adam G. Clause. LACM TC 1582 (tissue), PC 1656 (digital color photo). 21 December 2013. Adam G. Clause, James Erdman, Nicholas G. Buckmaster, Justin K. Clause. Natural History Museum of Los Angeles County (LACM 184466 [entire animal], TC 2058–2061, and PC 1721–1724). Verified by Gregory B. Pauly. Five salamanders were collected under rocks among herbaceous riparian vegetation, at two sites within the canyon. This is the twentieth known locality for this species range-wide, and just the seventh locality from the west-slope Inyo Mountains. It fills a ca. 5-km gap in the species' range (California Natural Diversity Database RareFind Data, California Department of Fish and Wildlife, 2013). Precise GPS coordinates for this record are held by the LACM, to prevent unauthorized disturbance of this protected species.

Work was approved under California Department of Fish and Wildlife Scientific Collecting Permit #011663 issued on 24 April 2013, Bureau of Land Management Bishop Field Office Permit #1110 (CA-170.31) issued on 24 January 2014 (retroactive), and University of Georgia IACUC AUP #A2012 10-004-Y1-A0 issued on 27 February 2013. Financial support provided by a University of Georgia Presidential Fellowship.

ADAM G. CLAUSE, Warnell School of Forestry and Natural Resources, University of Georgia, 180 East Green Street, Athens, Georgia 30602, USA (e-mail: adamclause@gmail.com); **JAMES ERDMAN** *and* **NICHOLAS G. BUCKMASTER**, California Department of Fish and Wildlife, 407 West Line Street, Room 1, Bishop, California 93514, USA; **CLEOPATRA TUDAY** *and* **NICKOLAS HUBEEK**, Moorpark College, 7075 Campus Road, Moorpark, California 93021, USA (e-mail: nhubeek@hotmail.com); **JUSTIN K. CLAUSE**, University of California-Davis, 1 Shields Avenue, Davis, California 95616, USA.

EURYCEA CHAMBERLAINI **(Chamberlain's Dwarf Salamander)**. USA: GEORGIA: Lamar Co.: Cherokee Drive in Barnesville (33.046534°N, 84.144869°W; WGS 84). 11 April 2013. Laura A. West. Verified by John Jensen. Gordon State College Collection of Vertebrates (GSC 048). New county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens, Georgia. 575 pp.). This species has not been documented in any of the adjoining counties (Jensen et al. 2008, *op. cit.*). Salamander was found alive beneath a plywood board during mid-afternoon.

Specimen collected under Georgia Department of Natural Resources Scientific Collecting Permit (29-WJH-13-126, CN 25018).

LAURA A. WEST (e-mail: lw125587@gordonstate.edu) and **GREGORY D. HARTMAN** Gordon State College, Barnesville, Georgia 30204, USA (e-mail: ghartman@gordonstate.edu).

EURYCEA CIRRIGERA **(Southern Two-lined Salamander)**. USA: TENNESSEE: Madison Co.: Jackson (35.61566°N, 88.87083°W; WGS84). 31 December 2013. Joshua M. Hall. Verified by A. Floyd Scott. Austin Peay State University Museum of Zoology (APSU 19473 [photo voucher]). New county record (Redmond and Scott 1996. [updated 2008; latest update: 11 November 2013]. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12. Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp. Available at http://www.apsu.edu/amatlas/, accessed 4 February 2014). One adult specimen found beneath fallen timber in a shallow wetland.

JOSHUA M. HALL 8146 East Denney Drive, Milan, Tennessee 38358, USA; e-mail: hallj@milanssd.org.

EURYCEA GUTTOLINEATA **(Three-lined Salamander)**. USA: GEORGIA: Floyd Co.: Unnamed spring adjacent to Morrison Campground (34.2758°N, 93.4175°W; WGS 84). 7 June 2000. N. Burkhead, R. Lewis, and C. Skelton. Verified by John Jensen. Georgia Museum of Natural History (GMNH 50654–50656). New county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575 pp.). Three adults were electroshocked out of thick beds of watercress during a fish survey. In this part of the state, the ranges of E. guttolineata and E. longicauda interdigitate and are not well-established, increasing the importance of this documented occurrence.

TODD PIERSON, Environmental Health Science, University of Georgia, Athens, Georgia, 30602, USA (e-mail: twpierso@uga.edu); **ADAM G. CLAUSE,** Warnell School of Forestry and Natural Resources, University of Georgia, Athens, Georgia 30602, USA (e-mail: adamclause@gmail.com); **TROY J. KIERAN**, Environmental Health Science, University of Georgia, Athens, Georgia 30602, USA (e-mail: kierant@uga.edu): **NIKOLE CASTLEBERRY,** Georgia Museum of Natural History, University of Georgia, Athens, Georgia 30602, USA (e-mail: neotoma@uga.edu).

EURYCEA GUTTOLINEATA **(Three-lined Salamander)**. USA: TENNESSEE: Madison Co.: Jackson (35.61485°N, 88.86722°W; WGS84). 31 December 2013. Joshua M. Hall. Verified by A. Floyd Scott. Austin Peay State University Museum of Zoology (APSU 19474 [photo voucher]). New county record (Redmond and Scott 1996. [updated 2008; latest update: 11 November 2013]. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12. Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp. Available at http://www.apsu.edu/amatlas/, accessed 4 February 2014). One adult specimen found beneath fallen timber in a shallow wetland.

***PSEUDOBRANCHUS AXANTHUS BELLI* (Everglades Dwarf Siren)**. USA: FLORIDA: Broward Co.: Water Conservation Area 3A (WCA-3A). (26.077°N, 80.714°W; WGS 84). Joshua Holbrook, Nathan Dorn, Natalie Knorp, and Alexander Chapman. Verified by Kenneth Krysko. FLMNH UF 171109. New county record (Krysko et al. 2011. Atlas of Amphibians and Reptiles in Florida. Final Report, Project Agreement 08013, Florida Fish and Wildlife Conservation Commission, Tallahassee. 524 pp.; Holbrook et al. 2012. Herpetol. Rev. 43:4) Nearest known records are from Miami-Dade Co. to the south, and multiple populations have been recently discovered in Palm Beach Co. to the north (Krysko et al. 2011, *op. cit.*; Holbrook et al. 2012, *op. cit.*). Eight individuals have been observed in WCA-3A in both Broward and Miami-Dade counties in ridge and slough habitat in January 2013. Individuals have been found in close proximity to predatory fish (e.g., centrarchids), though there is a profusion of emergent and floating vegetation, which may serve as refuge from potential predators. All specimens were captured as by-catch while sampling fishes and invertebrates with 1 m^2 throw traps.

JOSHUA D. HOLBROOK (e-mail: JHolbro8@fau.edu), **NATHAN J. DORN**, **NATALIE E. KNORP**, and **ALEXANDER D. CHAPMAN**, Department of Biological Sciences, Florida Atlantic University, Davie, Florida 33314, USA.

ANURA — FROGS

***ANAXYRUS PUNCTATUS* (Red-spotted Toad)**. MÉXICO: HIDALGO: Municipality of Tecozautla: La Guadalupe (20.530194°N, 99.588555°W; WGS84); 1946 m elev. 8 September 2012. Rafael Alejandro Calzada Arciniega. Verified by Luis Canseco Márquez. MZFC 27326. First record for Tecozautla, extending the range 20.5 km SW from the nearest locality at Cadereyta de Montes, Querétaro (Dixon and Lemos-Espinal. 2010. Amphibians and Reptiles of the State of Queretaro, México. Texas A&M University, College Station, Texas; UNAM, Tlalnepantla, México, México; CONABIO, México, D.F. ix + 428 pp.). The toad was in a canyon surrounded by xeric scrub vegetation.

RAFAEL ALEJANDRO CALZADA ARCINIEGA, Laboratorio de Herpetología, Facultad de Estudios Superiores Iztacala, Universidad Nacional Autónoma de México, Tlalnepantla, Estado de México 54090, México (e-mail: ralejandrocalzada89@gmail.com); **ALFONSO HERNÁNDEZ RÍOS**, Laboratorio de Herpetología, Instituto de Biología, Universidad Nacional Autónoma de México, Distrito Federal 04510, México (e-mail: alfonsohrios@gmail.com).

***CRAUGASTOR TALAMANCAE* (Almirante Robber Frog)**. REPUBLIC OF PANAMA: VERAGUAS: Cañazas District: ca. 20 m upstream from the mouth of Las Lajitas Creek where it enters San Pablo River (8.26334°N, 81.26404°W; WGS84), 78 m elev. 15 March 2013. V. Bravo and E. E. Flores. MVUP 2416. First record for the municipality and a 32 km SW range extension from the closest known locality at Alto de Piedra, Santa Fe District, in the central cordillera (Köhler 2011. Amphibians of Central America. Herpeton, Verlag Elke Köhler, Offenbach, Germany. 380 pp.). The frog was found at night on the bank of La Lajitas Creek; this species seems to be common along tributaries of the San Pablo River north of the Interamerican Highway. This project was conducted under the scientific permit (SE/A-26-13) provided by the Panamanian National Authority for the Environment (ANAM).

LEPTODACTYLUS CHAQUENSIS. BRAZIL: SANTA CATARINA: District of Curitibanos: Floodplain of Canoas River (27.4500°S, 50.6333°W; WGS 84). 09 September 2009. I. F. Machado. Amphibian Collection of Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre, Rio Grande do Sul, Brazil. PUCRS (MCP-Anfíbios 9983). Verified by G. M. Funk Pontes. Leptodactylus chaquensis is known from Argentina, Paraguay, Uruguay, lowland Bolivia, and from the Brazilian states of Acre, Mato Grosso, Mato Grosso do Sul, Minas Gerais, Paraná, Rio Grande do Sul, Rondônia, and São Paulo (Garcia and Vinciprova 1998. Herpetol Rev. 29[2]:117–118; Vasconcelos and Rossa-Feres 2005. Biota Neotrop. 5[2]:1–14; Calderon et al. 2009. Check List 5:425–427; Brassaloti et al. 2010. Biota Neotrop. 10[1]:1–17; Oda et al. 2014. Herpetoza 26:195–200). First state record, this new locality is situated among the known sites of the municipality Bossoroca in Rio Grande do Sul state (453 km SW), Guaíra in Paraná state (504 km NW), and the Gália and Alvilândia records in São Paulo state (563 km N).

IBERE FARINA MACHADO, Universidade Federal de Goiás, Instituto de Ciências Biológicas, Departamento de Ecologia, Prédio do ICB 1, Laboratório de Herpetologia e Comportamento Animal, Campus II/UFG, CEP 74001-970, Goiânia, Goiás, Brazil (e-mail: iberemachado@gmail.com); **RAFAEL GUSTAVO BECKER**, Biota Soluções Ambientais Ltda, rua Lindolfo Collor, n 439, Conj. 301, CEP 93010-080, São Leopoldo, RS, Brazil (e-mail: rafaelbecker@gmail.com); **ALEX SANDRO MESQUITA**, Biota Soluções Ambientais Ltda, rua Lindolfo Collor, n 439, Conj. 301, CEP 93010-080, São Leopoldo, RS, Brazil (e-mail: alexmeskita@gmail.com).

LEPTODACTYLUS MELANONOTUS **(Fringe-toed Foam Frog)**. REPUBLIC OF PANAMA: VERAGUAS: La Mesa District: ca. 67 m upstream from the mouth of El Corte Creek where it enters into San Pablo River (8.23352°N, 81.25976°W: WGS84), 66 m elev. 13 March 2013. V. Bravo and E. E. Flores. Verified by Andreas Hertz. MVUP 2414. First record for the district, extending the range of the species ca. 30 km SW of the closest known locality in Santa Fe District (Köhler 2011. Amphibians of Central America. Herpeton, Verlag Elke Köhler, Offenbach, Germany. 380 pp.), and also reduces the geographic gap on the Pacific versant between localities in southeastern Panama and south-central Costa Rica (Köhler 2011, *op. cit.*). The female frog was found at night on the muddy bank of El Corte Creek near water. This work was conducted under the scientific permit (SE/A-26-13) provided by the Panamanian National Authority for the Environment (ANAM).

ERIC ENRIQUE FLORES, Friends of Santa Fe National Park (AMIPARQUE), Apartado 0923-00126, Veraguas, Panama (e-mail: sailax1@gmail.com); **VÍCTOR BRAVO**, University of Panama, School of Biology, Panama City, Panama (e-mail: bravovictor50@yahoo.com); **JUNIER BARRÍA**, Community of Los Llanitos, La Mesa District, Panama.

LITHOBATES CATESBEIANUS **(American Bullfrog)**. MÉXICO: CHIHUAHUA: Municipality of Chihuahua: Río Chuvíscar (28.709860°N, 105.983975°W; WGS84), 1341 m elev. 10 October 2012. Rubén Alonso Carbajal Márquez and Martín Lara. Verified by Lee Grismer. La Sierra University Digital Photo Collection (LSUDPC 6659). First municipality record, extending the known range of the species ca. 269 km (airline) SE from the closest known locality, 2.1 km NW Nuevo Casas Grandes, Municipality of Nuevo Casas Grandes, Chihuahua (Lemos-Espinal and Smith 2009. Anfibios y Reptiles del Estado de Chihuahua, México, 2nd ed. UNAM, Tlalnepantla, México, México; Univ. of Colorado, Boulder; CONABIO, México, D.F. 613 pp.). The frog was found at 2125 h foraging in the river along with other adults and young.

RUBÉN ALONSO CARBAJAL-MÁRQUEZ, Centro de Investigaciones Biológicas del Noroeste, Mar Bermejo #195 Col. Playa Palo de Santa Rita, C.P. 23090, La Paz, Baja California Sur, México (e-mail: redman031@hotmail.com); **ZAIRA YANETH GONZÁLEZ-SAUCEDO**, Universidad Autónoma de Querétaro, Facultad de Ciencias, Av. de la Ciencias S/N, Col. Juriquilla, C.P. 76230, Querétaro, Qro., México; **JOSÉ CARLOS ARENAS-MONROY**, Universidad Autónoma de Aguascalientes, Ciudad Universitaria, C.P. 20100, Aguascalientes, Ags. México; **MARTÍN LARA**, Juan Mata Ortíz, #4042, C.P. 32230, Ciudad Juárez, Chihuahua, México.

LITHOBATES CATESBEIANUS **(American Bullfrog)**. MÉXICO: CHIHUAHUA: Municipio Saucillo: Presa Rosetilla (28.2547°N, 105.298753°W; WGS84), 1138 m elev. 9 August 2000. Cesar Muñoz-Rivas and Ana Gatica-Colima. Verified by Héctor Gadsden-Esparza. Sección Herpetológica, Colección Científica de Vertebrados, Universidad Autónoma de Ciudad Juárez, (CCV-UACJ 157–160). First record for the municipality and range extension of ca. 360 airline km SE from the nearest record in Chihuahua, 2.1 km NW Nuevo Casas Grandes (Lemos and Smith 2007. Anfibios y Reptiles del Estado de Chihuahua, México. UNAM, Tlanepantla, México 54090, México and CONABIO, D.F. 14010, México. xiii + 613 pp.). There seems to be an established population at this Presa Rosetilla site, as a second visit to the area during 19–20 June 2003 found four more bullfrogs (CCV-UACJ 420, 427–429). The bullfrog is considered an exotic invasive species that is a ravenous predator of small native wetland animals, so its expanding range in Chihuahua is a cause of concern. Although 1981 records of bullfrogs (e.g., CNAR [IBH] 3998) exist from La Boquilla, Lago Colina, Chihuahua (Casas-Andreu et al. 2001. Ciencia Ergo Sum 8:6–67), Lemos and Smith (2007, *op. cit.*) did not include any La Boquilla records.

Collecting permits were kindly issued by the Dirección General de Vida Silvestre, SEMARNAT (#1445 and #1553).

LITHOBATES CLAMITANS **(Green Frog)**. USA: ALABAMA: Crenshaw Co.: wetland 30 m N of Crenshaw County Rd. 30 and 160 m E of Piney Woods Creek (31.84732°N, 86.21375°W; WGS 84). 03 July 2013. M. Herr and S. Graham. Verified by David Laurencio. AUM AHAP-D 751 (digital photo voucher). New county record (Mount 1975. The Reptiles and Amphibians of Alabama. Auburn Printing Co., Auburn. 347 pp.).

Funding was provided by a Penn State Office of Undergraduate Education Summer Discovery Grant to Mark Herr and a National Science Foundation grant (IOS-1051367, DEB- 0949483) to Tracy Langkilde.

MARK W. HERR (e-mail: mwh5426@psu.edu), Department of Biology, Pennsylvania State University, 208 Mueller Laboratory, University Park,

Pennsylvania 16802, USA; **SEAN P. GRAHAM**, Department of Biology, University of Findlay, 1000 N. Main St., Findlay, Ohio 45840, USA.

***OSTEOPILUS SEPTENTRIONALIS* (Cuban Treefrog)**. USA: LOUISIANA: Jefferson Parish: Bridge City. Animal found in a nursery (29.935453ºN, 90.170697ºW; WGS 84). 30 June 2013. Matt Vance. Verified Eric Rittmeyer. Louisiana State University Museum of Natural Science (LSUMZ 98143). First state record (Dundee and Rossman 1989. Amphibians and Reptiles of Louisiana. Louisiana State University Press, Baton Rouge. 300 pp.).

A single, gravid female was found on a horticultural plant (*Lagerstroemia*; crepe myrtle). Although not indicative of an established population, the discovery of this highly invasive species in Louisiana is cause for concern (McGarrity and Johnson 2009. Biol. Invas. 11:1411–1420; Rödder and Weinsheimer 2009. J. Nat. Hist. 43:1207–1217). The animal was alive and seemingly healthy at the time of collection.

Indigenous to many Caribbean islands, *O. septentrionalis* has been established in Florida at least since 1928 (Barbour 1931. Copeia 1931:140) where it likely has negative impacts on native species (Smith 2005. Biol. Conserv. 123:433–441; Rice et al. 2011. Herpetologica 67:105–117) and is considered highly invasive. Individuals have been reported in Georgia (Johnson 2007. Herpetol. Rev. 38:349; Jensen et al. 2008. Amphibians and Reptiles of Georgia, University of Georgia Press), Maryland (Meshaka 1996. Herpetol. Rev. 27:37–40), Colorado (Livo et al. 1998. Northwest. Nat. 79:1–11), Virginia (Mitchell 1999. Catesbeiana 19:32), and Canada (Meshaka 1996. Herpetol. Rev. 27:37–40) but, like the individual described here, were probably recent imports and, therefore, do not represent established populations.

MATTHEW W. H. CHATFIELD, Tulane-Xavier Center for Bioenvironmental Research, Tulane University, New Orleans, Louisiana 70115, USA (e-mail: mattchat@tulane.edu); **MATT VANCE**, Louisiana Outdoor Outreach Program, Office of State Parks, New Orleans, Louisiana 70124, USA (e-mail: mvance@crt.la.gov).

***PSEUDACRIS CRUCIFER* (Spring Peeper)**. USA: GEORGIA: Peach Co.: Lakeview Rd, 6.3 km S of Byron (32.58892°N, 83.7711632°W; WGS 84). 26 November 2013. S. Graham and C. K. Graham. Verified by David Laurencio. AUM AHAP-D 00775 (digital photo voucher). New county record (Jensen et al. 2008. The Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575 pp.).

SEAN P. GRAHAM, Department of Biology, University of Findlay, 1000 N. Main St., Findlay, Ohio 45840, USA (email: graham@findlay.edu); **CRYSTAL KELEHEAR GRAHAM**, School of Biological Sciences, University of Sydney, Camperdown, New South Wales, Australia.

***RHINELLA MARINA* (Cane Toad)**. USA: FLORIDA: Gilchrist Co.: 5880 NE 70th Street, High Springs, Florida (29.84403°N, 82.71016°W; WGS84; elev. 19.5 m). 28 May 2012. Peter L. Butt. Verified by Kenneth L. Krysko. Florida Museum of Natural History (UF 166746). New county record (Krysko et al. 2011. Atlas of Amphibians and Reptiles in Florida. Final Report, Florida Fish and Wildlife Conservation Commission, Tallahassee. 524 pp.). Female (SVL = 132 mm, mass = 374 g) captured by hand at 2000 h. This non-indigenous species has been reproducing in southern Florida since the 1950s (Duellman and Schwartz 1958. Bull. Florida State Mus. 3:181–324), but a large distribution gap (>150 km) exists between the well-established southern Florida population and the specimen we report. Specimens are also known from Clay and Columbia counties in northern Florida (Krysko et al. 2011, *op. cit.*), but there is no evidence of an established population in this area.

CODY GODWIN, University of Florida, Gainesville, Florida 32611, USA (e-mail: codydg1dwin@ufl.edu); **GERALD R. JOHNSTON**, Department of Natural Sciences, Santa Fe College, Gainesville, Florida 32606, USA (e-mail: jerry.johnston@sfcollege.edu); **PETER L. BUTT** (e-mail: kes@atlantic.net) and **GEORGIA A. SHEMITZ** (e-mail: kes@atlantic.net), Karst Environmental Services, High Springs, Florida 32643, USA; **ADRIENNE DRENNEN**, Santa Fe College, Gainesville, Florida 32606, USA (e-mail: adrenn1@gmail.com).

***RHINELLA MARINA* (Cane Toad)**. USA: FLORIDA: Orange Co.: Apopka, 625 W. Keene Road (28.640233°N, 81.52361°W, WGS 84). 30 January 2014. Bryce Merritt. Verified by Kenneth L. Krysko. Florida Museum of Natural History, University of Florida (UF-Herpetology 172560). Second county record (Krysko et al. 2011a. Atlas of Amphibians and Reptiles in Florida. Final Report, Project Agreement 08013, Florida Fish and Wildlife Conservation Commission, Tallahassee. 524 pp.).

One adult male (SUL = 110 mm) collected from inside propagation house of a horticultural business, and originally turned in to Division of Plant Industry, Florida Department of Agriculture and Consumer Services, Gainesville, Florida; Entomology Log No. E2014-874-1. A subsequent survey of this area of Apopka, by one of us (BM), failed to locate additional specimens.

Over 34 years ago a specimen (UCF 0485) was collected from Fort Wilderness, Walt Disney World, Orlando, on 2 November 1979 approximately 29.77 km to the SSW.

Rhinella marina is indigenous to Central and South America, Mexico, and extreme southern Texas, USA, but has a large worldwide nonindigenous distribution primarily due its misguided use as a biocontrol for insect pests (Easteal 1981. Biol. J. Linn. Soc. 16:93–113; Lever 2001. The Cane Toad: The History and Ecology of a Successful Colonist. Westbury Publishing, Otley, England. 230 pp.; Kraus 2009. Alien Reptiles and Amphibians: A Scientific Compendium and Analysis. Springer, Dordrecht. 563 pp. + CD-Rom; Somma 2011. *In* Fuller [ed.], Nonindigenous Aquatic Species. USGS: http://nas.er.usgs.gov/queries/FactSheet.aspx?speciesID=48; Powell and Henderson [eds.] 2012. Bull. Florida Mus. Nat. Hist. 51:85–166).

In Florida, *R. marina* was originally introduced to control sugarcane pests (Lobdell 1936. Univ. Florida Agric. Exp. Station Annu. Rept. 1936:123–124), and other subsequently successful introductions were made through the pet trade and a zoo release (King and Krakauer 1966. Quart. J. Florida Acad. Sci. 29:144–154; Himes 2007. Herpetol. Rev. 38:473; Krysko et al. 2011b. Zootaxa 3028:1–64). Thus, *R. marina* is established in at least 16 counties in Florida (Krysko et al. 2011a, *op. cit.*; Meshaka 2011. Herpetol. Conserv. Biol. [Monogr. 1] 6:i–iii, 1–101 pp.). Currently, we are unable to determine if our specimen is a single individual brought in through horticultural products or if it represents an undetected, established population in Orange Co. As the nearest populations of *R. marina* occur in adjacent Polk and Brevard counties, to the southwest and east, respectively (Krysko et al. 2011a, *op. cit.*; Meshaka 2011, *op. cit.*), we suggest monitoring to prevent further spread of this invasive, ecologically destructive species in Central Florida.

LOUIS A. SOMMA, Florida Museum of Natural History, University of Florida, Gainesville, Florida 32611, USA (e-mail: somma@ufl.edu); **BRYCE MERRITT**, Division of Plant Industry, Florida Department of Agriculture and Consumer Services, 1010 Ocoee-Apopka Rd., Suite 500, Apopka, Florida 32703, USA (e-mail: bryce.merritt@freshfromflorida.com).

***SCAPHIOPUS HOLBROOKII* (Eastern Spadefoot)**. USA: GEORGIA: Peach Co.: Lakeview Rd, 6.3 km S of Byron (32.58892°N, 83.7711632°W; WGS 84). 26 November 2013. S. Graham and C. K. Graham. Verified by David Laurencio. AUM AHAP-D 00774 (digital photo voucher). New county record (Jensen et al. 2008. The Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575 pp.).

Washington Co.: South side of Prosser Rd. (Prosser Rd. forms the boundary between Washington Co. and Hancock Co.), 100 m W of Friendship (33.08128°N, 83.03645°W; WGS 84). 22 December 2013. S. Graham and C. K. Graham. Verified by David Laurencio. AUM AHAP-D 00776 (digital photo voucher). New county record (Jensen et al. 2008, *op. cit.*).

CROCODILIA — CROCODILIANS

***ALLIGATOR MISSISSIPPIENSIS* (American Alligator)**. USA: ALABAMA: Bullock Co.: Wehle Tract, 6.75 km SE of Midway (32.03090°N 85.47132°W; WGS 84). 11 March 2014. C. Thawley and F. Graves. Verified by David Laurencio, AUM AHAP-D 782 (digital photograph file). New county record (Mount 1975. The Reptiles and Amphibians of Alabama. Auburn Printing Co., Auburn. 347 pp.). Numerous individuals were observed in a pond, including juveniles, indicating reproduction on site. This record fills a distributional gap along the species' northern range limit in Alabama, where verified records are scarce, with the nearest vouchered localities approximately 42 km SE in Barbour Co. and 156 km WNW in Dallas Co..

CHRISTOPHER J. THAWLEY, Department of Biology, Pennsylvania State University, 208 Mueller Laboratory, University Park, Pennsylvania 16802, USA (e-mail: cthawley@gmail.com); **FERN GRAVES,** School of Forestry and Wildlife Sciences, Auburn University, Auburn, Alabama 36849, USA (e-mail: fbg0002@auburn.edu).

TESTUDINES — TURTLES

***APALONE MUTICA* (Smooth Softshell Turtle)**. USA: MISSOURI: Perry Co.: Brazeau Township. Found near bank of Mississippi River, 10 m E of BNSF railroad and 0.5 km NW of Cottonwood Island (37.6117°N, 89.5169°W; WGS84). 2 July 2013. Andrew P. Braun and John West. Verified by Dustin S. Siegel. University of Missouri-Columbia (UMC 2392P). Male specimen, captured in fyke net. New county record (Edmond and Daniel 2013 [latest update: 5 April 2013]). Missouri Herpetological Atlas Project. Available at http://atlas.moherp.org/; accessed 9 July 2013).

ANDREW P. BRAUN (e-mail: Andrew.Braun@mdc.mo.gov) and **JOHN WEST**, Open Rivers & Wetlands Field Station, Missouri Department of Conservation, Jackson, Missouri 63755, USA.

***APALONE SPINIFERA* (Spiny Softshell)**. USA: INDIANA: Hamilton Co.: Conner Prairie Interactive History Park (39.9816°N, 86.0334°W; WGS 84). 8 June 2013. Robert Brodman, Michael S. Finkler, James Horton, Megan Gramhofer, and Anastasia Marsh. Verified by Alan Resetar. Photo voucher Saint Joseph's College zoological collection (SJCZC R321). New county record (Minton 2001. Amphibians & Reptiles of Indiana, 2nd ed. Indiana Academy of Science, Indianapolis. 404 pp.). Extends range into a nine-county gap 13 km N from nearest known locality in Marion Co.

ROBERT BRODMAN (e-mail bobb@saintjoe.edu), **MEGAN GRAMHOFER** and **ANASTASIA MARSH,** Biology Department, Saint Joseph's College, Rensselaer, Indiana 47978, USA; **MICHAEL S. FINKLER,** School of Sciences, Indiana University Kokomo, PO Box 9003, Kokomo, Indiana 46904-9003, USA (e-mail: mfinkler@iuk.edu); **JAMES HORTON,** 10 Catalina Circle, Zionsville, Indiana 46077, USA (e-mail: stardali84@hotmail.com).

***APALONE SPINIFERA* (Spiny Softshell)**. USA: TENNESSEE: Henderson Co.: Darden (35.69640°N, 88.23756°W; WGS84). 1 July 2013. Joshua M. Hall. Verified by A. Floyd Scott. Austin Peay State University Museum of Zoology (APSU 19472 [photo voucher]). New county record (Scott and Redmond 2008. [updated 10 January 2014]. Atlas of Reptiles in Tennessee. The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. Available at http://www.apsu.edu/reptatlas/, accessed 4 February 2014). Voucher specimen was an adult male caught on fishing line.

JOSHUA M. HALL, 8146 East Denney Drive, Milan, Tennessee 38358, USA; e-mail: hallj@milanssd.org.

***CHELYDRA SERPENTINA* (Snapping Turtle)**. USA: INDIANA: Lawrence Co.: Avoca State Fish Hatchery (38.910419°N, 86.550433°W; NAD 83). 15 October 2013. Sarabeth Klueh-Mundy and Jason Mirtl. Verified by Chris Phillips. Illinois Natural History Survey (INHS 2013f photo voucher). New county record for Indiana (Minton 2001. Amphibians and Reptiles of Indiana. 2nd ed., revised. Indiana Academy of Science, Indianapolis. vii + 404 pp.). Found in a fish-rearing pond.

SARABETH KLUEH-MUNDY (e-mail: sklueh-mundy@dnr.IN.gov) and **JASON MIRTL**, Wildlife Diversity Program, Indiana Department of Natural Resources Division of Fish and Wildlife, 5596 East State Road 46, Bloomington, Indiana 47401, USA.

***CHRYSEMYS PICTA* (Painted Turtle)**. USA: Alabama: Bibb Co.: Found crossing U.S. 82 in Eoline (32.994498°N, 87.230959°W; WGS84). 10 May 2009. Peter V. Lindeman. Verified by James C. Godwin. Florida Museum of Natural History Herpetology Dept. photographic archive (UF 172128, two photos). New county

record (Mount 1975. The Reptiles and Amphibians of Alabama. Auburn Univ. Agric. Exp. Sta., Auburn, Alabama. 347 pp.). Animal was oriented eastward toward a small pond.

Mount (*op. cit.*) mapped numerous records for the species in Alabama, but none for an 18-county area in the central part of the state, including all six counties contiguous with Bibb Co., hence the new record occurs in the center of the large area of the range he depicted as unoccupied in his range map for the species. The new record calls into question the large range gap shown for the species in central Alabama by Mount and subsequent sources (e.g., Conant and Collins 1991. A Field Guide to Reptile & Amphibians: Eastern and Central North America, 3rd ed. Houghton Mifflin Co., Boston, Massacusetts. 616 pp.; Ernst and Lovich 2009. Turtles of the United States and Canada, 2nd ed. Johns Hopkins Univ. Press, Baltimore, Maryland. 827 pp.).

The new locality and others that may yet be discovered in the central region of Alabama may be vitally important for resolving the question of whether or not the taxon *dorsalis* should be regarded as a separate species or a subspecies of *C. picta*. Ernst (1967. Copeia 1967:131–136) analyzed morphological variation from Arkansas and Louisiana to Georgia and concluded that nearly half of the Alabama specimens he examined were intergrades of two subspecies, *C. p. picta* from the east and *C. p. dorsalis* from the west. Mount considered the region of Alabama east of the Coosa River, beginning ca. 67 km E of the new Bibb Co. record, to be an area of intergradation of the subspecies *C. p. picta* from the east, *C. p. marginata* from the north, and *C. p. dorsalis* from the west (see also Conant and Collins, *op. cit.*). On the basis of mtDNA sequences, Starkey et al. (2003. Evolution 57:119–128.) concluded that *dorsalis* warranted separate species status; two specimens from one site in northern Alabama were sampled and were grouped in a *dorsalis* clade that was strongly supported as sister to a clade of all other *C. picta*. Their conclusion has not been universally accepted (e.g., Ernst and Lovich, *op. cit.*; Fritz and Havaš 2007. Vert. Zool. 57:149–368; Rhodin et al. 2010. Chelon. Res. Monogr. 5:000.85–000.164). The two photos of the Bibb Co. specimen show characters consistent with *C. p. dorsalis*: lack of a dark plastral pattern, a wide reddish-orange dorsal stripe, and relatively strong misalignment of the costal and vertebral scute margins (Ultsch et al. 2001. Can. J. Zool. 79:485–498). Genetic sampling and morphological analysis of painted turtles from central Alabama would be of strong interest in resolving the taxonomic status of painted turtles in the southern United States.

PETER V. LINDEMAN, Department of Biology and Health Services, 126 Cooper Hall, Edinboro University of Pennsylvania, Edinboro, Pennsylvania 16444, USA; e-mail plindeman@edinboro.edu.

***GRAPTEMYS OCULIFERA* (Ringed Map Turtle)**. USA: MISSISSIPPI: Pike Co.: Bogue Chitto River, Hwy. 44 bridge east of McComb (31.269688°N, 90.361556°W; WGS84). 27 May 2013. Peter V. Lindeman. Verified by Will Selman. Florida Museum of Natural History (UF 172126 photographic voucher). New county record (Lindeman 2013. The Map Turtle and Sawback Atlas: Ecology, Evolution, Distribution, and Conservation. Univ. Oklahoma Press, Norman. 460 pp.). Extends the range of the species in the Bogue Chitto River 19.9 km NW and ca. 30 river km above the previous most upstream vouchered record, in Walthall Co.

PETER V. LINDEMAN, Department of Biology and Health Services, 126 Cooper Hall, Edinboro University of Pennsylvania, Edinboro, Pennsylvania 16444, USA; e-mail plindeman@edinboro.edu.

***GRAPTEMYS OUACHITENSIS* (Southern Map Turtle)**. USA: ARKANSAS: Baxter Co.: Lakeview Boat Dock (36.370576°N, 92.554544°W; WGS 84). 25 May 2013. M. B. Connior. Verified by S. E. Trauth. Arkansas State University Museum of Zoology Herpetology Collection (ASUMZ 33041). New county record (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. University of Arkansas Press, Fayetteville. 421 pp.). This juvenile (carapace length [cl] = 57 mm) is a new county record; yet, this species has been captured in the same body of water (Bull Shoals Lake) in adjacent Marion Co.

MATTHEW B. CONNIOR, Health and Natural Sciences, South Arkansas Community College, El Dorado, Arkansas 71731, USA (e-mail: mconnior@southark.edu); **CHRIS T. MCALLISTER** Science and Mathematics Division, Eastern Oklahoma State College, Idabel, Oklahoma 74745, USA (e-mail: cmcallister@se.edu).

***GRAPTEMYS PEARLENSIS* (Pearl River Map Turtle)**. USA: MISSISSIPPI: Lincoln Co.: Bogue Chitto River, Bogue Chitto Rd. SE east of Bogue Chitto (31.438606°N, 90.446853°W; WGS84). 27 May 2013. Peter V. Lindeman. Basking hatchling. Florida Museum of Natural History (UF 172124 photographic voucher). Verified by Will Selman. New county record (Lindeman 2010. Herpetol. Rev. 41:105; Lindeman 2013. The Map Turtle and Sawback Atlas: Ecology, Evolution, Distribution, and Conservation. Univ. Oklahoma Press, Norman. 460 pp.). Extends the range of the species in the Bogue Chitto River 33.5 km NW and 58 river km above the previous most upstream vouchered record in Pike Co. A second specimen (UF 172125 photo voucher) was also found.

PETER V. LINDEMAN, Department of Biology and Health Services, 126 Cooper Hall, Edinboro University of Pennsylvania, Edinboro, Pennsylvania 16444, USA; e-mail plindeman@edinboro.edu.

***GRAPTEMYS PSEUDOGEOGRAPHICA KOHNII* (Mississippi Map Turtle)**. USA: ARKANSAS: Poinsett Co.: Bearitage Farms, 4.25 km S. of State Hwy 214 (35.446727°N, 90.797688°W; NAD 83). 20 Sept 2010. P. Jordan, J. Czerwonky, P. Dill, and J. Myer. Verified by S. E. Trauth. Arkansas State University Museum of Zoology (ASUMZ 31563). New county record (Trauth et al. 2004. Amphibians and Reptiles of Arkansas. Univ. of Arkansas Press, Fayetteville. 421 pp.); known from many other counties throughout Arkansas.

PHILLIP N. JORDAN, 1607 Tanglewood Drive, Jonesboro, Arkansas 72401, USA; e-mail: phillipnjordan03@hotmail.com.

***KINOSTERNON SUBRUBRUM* (Eastern Mud Turtle)**. USA: ALABAMA: Dallas Co.: Hwy 14, 6.3 km E of Selma and 550 m E of Indian Way intersection (32.4319166°N, 86.9579444°W; WGS84). 22 August 2009. Peter V. Lindeman. Verified by James C. Godwin. Florida Museum of Natural History (UF 172294 photographic voucher). New county record (Mount 1975. The Reptiles and Amphibians of Alabama. Auburn Univ. Agric. Exp. Sta., Auburn, Alabama. 347 pp.). Specimen found crossing road.

PETER V. LINDEMAN, Department of Biology and Health Services, 126 Cooper Hall, Edinboro University of Pennsylvania, Edinboro, Pennsylvania, 16444, USA; e-mail: plindeman@edinboro.edu.

***PELODISCUS SINENSIS* (Chinese Softshell Turtle)**. PHILIPPINES: MINDANAO ISLAND: South Cotabato Province: Koronadal City, Barangay Zone 3 (6.492400°N, 124.841683°E; WGS 84). 17 July 2012. Emerson Y. Sy. Photographic voucher, Raffles Museum of Biodiversity Research, National University of Singapore (ZRC [IMG] 2.218a–c). Verified by Indraneil Das. Observed in Bulok

Creek. SCL 28 mm. First provincial record. An introduced species in the Philippines, previously recorded on Luzon, Mindoro, Panay, Cebu, Bohol, Leyte, and Mindanao (Diesmos et al. 2008. Chelon. Conserv. Biol. 7:157–177; Sy et al. 2004. Turtle & Tortoise Newsl. 7:17–18). Record extends distribution by ca. 309 km from Zamboanga City, the first record on Mindanao.

EMERSON Y. SY, Philippine Center for Terrestrial and Aquatic Research, 1198 Benavidez St., Unit 1202, Tondo, Manila, Philippines; e-mail: emersonsy@gmail.com.

***PSEUDEMYS CONCINNA* (River Cooter)**. USA: ALABAMA: Choctaw Co.: Two-track dirt road next to Okatuppa Creek (31.8306833°N, 88.2291138°W; WGS 84). 27 May 2008. Peter V. Lindeman. Verified by James C. Godwin. Florida Museum of Natural History (UF 153480 photographic voucher). New county record (Mount 1975. The Reptiles and Amphibians of Alabama. Auburn Univ. Agric. Exp. Sta., Auburn, Alabama. 347 pp.). Nesting adult female.

PETER V. LINDEMAN, Department of Biology and Health Services, 126 Cooper Hall, Edinboro University of Pennsylvania, Edinboro, Pennsylvania 16444, USA; e-mail plindeman@edinboro.edu.

***PSEUDEMYS NELSONI* (Florida Red-bellied Cooter)**. USA: FLORIDA: Suwannee Co.: Ichetucknee Springs State Park, Ichetucknee River near W bank 3 km NE of the Highway 27 bridge crossing (29.96922°N, 82.76069°W; WGS84). 22 February 2014. Jonathan D. Mays. Verified by Kenneth L. Krysko. Florida Museum of Natural History (UF 172555 photo voucher). New county record (Krysko et al. 2011. Atlas of Amphibians and Reptiles in Florida. Final report, Florida Fish and Wildlife Conservation Commission, Tallahassee. 524 pp.). I observed one basking adult while canoeing the spring run through a wide marshy area. A previous study reported *P. nelsoni* from the Ichetucknee (Chapin and Meylan 2010. Herpetol. Conserv. Biol. 6:51–60), but no museum vouchers were submitted for either Columbia or Suwannee counties, which are divided by the Ichetucknee River.

JONATHAN D. MAYS, Florida Fish and Wildlife Conservation Commission, 1105 S.W. Williston Road, Gainesville, Florida 32601, USA; e-mail: jonathan.mays@myfwc.com.

***TRACHEMYS SCRIPTA ELEGANS* (Red-eared Slider)**. USA: INDIANA: Hamilton Co.: Conner Prairie (39.9820°N, 86.0309°W; WGS 84). 9 June 2013. Robert Brodman, Michael S. Finkler, James Horton, Megan Gramhofer, and Anastasia Marsh. Verified by Alan Resetar. Saint Joseph's College zoological collection (SJCZC R322). New county record (Minton 2001. Amphibians & Reptiles of Indiana, 2nd ed. Indiana Academy of Science, Indianapolis. 404 pp.). Extends range into a nine county gap 13 km N from nearest known locality in Marion County.

ROBERT BRODMAN (e-mail bobb@saintjoe.edu), **MEGAN GRAMHOFER** and **ANASTASIA MARSH,** Biology Department, Saint Joseph's College, Rensselaer, Indiana 47978, USA; **MICHAEL S. FINKLER,** School of Sciences, Indiana University Kokomo, PO Box 9003, Kokomo, Indiana 46904-9003, USA (e-mail: mfinkler@iuk.edu); **JAMES HORTON,** 10 Catalina Circle, Zionsville, Indiana 46077, USA (e-mail: stardali84@hotmail.com).

***TRACHEMYS SCRIPTA SCRIPTA* X *ELEGANS* (Pond Slider intergrade)** USA: Pennsylvania: Berks Co.: Reading, Carsonia Park (40.337691°N, 75.872571°W; WGS84). 21 Sept 2013. Carl Maiese. Verified by Walter Meshaka. Kutztown University Museum of Zoology (KUMZ 1001). New county record (Hulse et al. 2001. Amphibians and Reptiles of Pennsylvania. Cornell University Press, Ithaca, New York. 419 pp.). The online Pennsylvanian Amphibian and Reptile Survey (PARS, http://www.paherpatlas.org [accessed 8 Oct 2013]) noted *Trachemys scripta elegans* (online photo voucher only) and *Trachemys scripta* (no subspecific designation) observations, but *T. scripta scripta* and T. *scripta scripta* × *elegans* have not been confirmed from Berks Co. One *T. scripta* photographic entry from PARS suggested a possible *T. s. elegans* × *T. scripta* observation; however, our specimen is the first verified *T. s. scripta* × *T. s. elegans* intergrade documented in this county for which there is a preserved voucher. The male turtle was found in a pond in Carsonia Park; subsequent surveys uncovered an additional specimen and suggests that a breeding population of this introduced species has been established at this site.

CARL MAIESE (e-mail: cmaie796@live.kutztown.edu) and **MATTHEW STONE** (e-mail: stone@kutztown.edu), Department of Biology, Kutztown University, P.O. Box 730, Kutztown, Pennsylvania 19530, USA.

***TRACHEMYS SCRIPTA SCRIPTA* (Yellow-bellied Slider)**. USA: ALABAMA: Bullock Co.: basking in pond on the Wehle Tract, 8.4 km W of Comer, Alabama (32.03081°N 85.47115°W; WGS 84). 11 March 2014. C. Thawley and F. Graves. Verified by David Laurencio. AUM AHAP-D 785–786 (digital photograph files). New county record (Mount 1975. The Reptiles and Amphibians of Alabama. Auburn Printing Co., Auburn, Alabama. 347 pp.). This record fills a distributional gap between the nearest vouchered localities approximately 10 km E in Barbour Co. and 29 km N in Macon Co.

THAWLEY, Department of Biology, Pennsylvania State University, 208 Mueller Laboratory, University Park, Pennsylvania 16802, USA (e-mail: cthawley@gmail.com); **FERN GRAVES,** School of Forestry and Wildlife Sciences, Auburn University, Auburn, Alabama 36849, USA (e-mail: fbg0002@auburn.edu).

SQUAMATA — LIZARDS

***AMPHISBAENA FULIGINOSA* (Speckled Worm Lizard)**. BRAZIL: AMAPÁ: Municipality of Laranjal do Jari: Água Branca do Cajari (0.578314°S, 52.326769°W, 136 m elev.; datum WGS84) 10 July 2013. C. E. Costa-Campos, D. W. Silva-Silva, and K. J. Gaya Corrêa. Verified by A. P. Lima. Collection of Laboratório de Zoologia of the Universidade Federal do Amapá, Macapá, Amapá, Brazil (CDLABZOO 28, photo voucher). Amphisbaena fuliginosa was known previously from Panama, Peru, Ecuador, Colombia, Bolivia, Guyana, Suriname, Trinidad, and Brazil (Vanzolini 2002. An. Acad. Bras. Ciênc. 74[4]:609–648). In Brazil, the species was reported in the states of Pará (Ávila-Pires et al. 2010. Bol. Mus. Para. Emílio Goeldi 5[1]:13–112), Goiás (Colli et al. 2002. In Oliveira and Marquis [eds.], The Cerrado of Brazil: Ecology and Natural History of a Neotropical Savanna, pp. 223–241. Columbia University Press, New York), Minas Gerais (Silveira 2007. Herpetol. Rev. 38[4]:481; Nogueira-Costa et al. 2013. Check List 9[1]:167–168), Maranhão, Mato Grosso, Rondônia, Roraima, and Manaus (Vanzolini, *op. cit.*). First state record, extending the range 325 km NW from the municipality of Alenquer, Para state.

CARLOS E. COSTA-CAMPOS (e-mail: eduardocampos@unifap.br), **DANIEL WELTON SILVA-SILVA** (e-mail: dan.ws@hotmail.com), and **KELLY JULIANA GAYA CORRÊA** (e-mail: kelly__juliana@hotmail.com), Laboratório de Herpetologia, Departamento de Ciências Biológicas e da Saúde, Universidade Federal do Amapá, Campus Marco Zero, CEP 68903-419, Macapá, AP, Brazil.

AMPHISBAENA IGNATIANA. BRAZIL: PARAÍBA: Municipality of João Pessoa: 7.1653°S, 34.8694°W. May 1984. Verified by S. da Silva.

Departamento de Sistemática e Ecologia da Universidade Federal da Paraíba, João Pessoa, Brazil (CHUFPB 5454). Previously known only from the type locality Santo Inácio municipality (11.1000°S, 42.7333°W), state of Bahia (Vanzolini 1991. Pap. Avul. Zool. 37[17]:259–276), in the east side of the São Francisco River. First state record, extends the known distribution of the species ca. 970 km NE from type locality. Furthermore, João Pessoa is situated in the west side of the São Francisco River, which suggests that the river is not a barrier for this species.

GESIKA D. A. MATIAS, Programa de Pós-Graduação em Diversidade Biológica e Conservação nos Trópicos, Instituto de Ciências Biológicas e da Saúde, Universidade Federal de Alagoas, Campus A. C. Simões, Avenida Lourival Melo Mota, s/n, Cidade Universitária, CEP: 57072-900, Maceió, Alagoas, Brazil (e-mail: gesikaamatias@hotmail.com); **GUSTAVO H. C. VIEIRA**, Departamento de Sistemática e Ecologia, Centro de Ciências Exatas e da Natureza, Universidade Federal da Paraíba, Cidade Universitária, CEP: 58051-900, João Pessoa, Paraíba, Brazil (e-mail: ghcvieira@dse.ufpb.br); **TAMÍ MOTT**, Setor de Biodiversidade e Conservação, Instituto de Ciências Biológicas e da Saúde, Universidade Federal de Alagoas, Campus A. C. Simões, Avenida Lourival Melo Mota, s/n, Cidade Universitária, CEP: 57072-900, Maceió, Alagoas, Brazil (e-mail: tamimott@hotmail.com).

***ANOLIS CAROLINENSIS* (Green Anole)**. USA: ALABAMA: Bullock Co.: The Wehle Tract, 7.9 km W of Comer (32.02959°N 85.46646°W; WGS 84). 11 March 2014. C. Thawley and F. Graves. Verified by David Laurencio. AUM AHAP-D 783 (digital photograph file). New county record (Mount 1975. The Reptiles and Amphibians of Alabama. Auburn Printing Co., Auburn, Alabama. 347 pp.). This record fills a distributional gap among the nearest vouchered localities approximately 46 km WSW in Pike Co., 33 km E in Barbour Co., and 35 km NE in Russell Co.

CHRISTOPHER J. THAWLEY, Department of Biology, Pennsylvania State University, 208 Mueller Laboratory, University Park, Pennsylvania 16802, USA (e-mail: cthawley@gmail.com); **FERN GRAVES**, School of Forestry and Wildlife Sciences, Auburn University, Auburn, Alabama 36849, USA (e-mail: fbg0002@auburn.edu).

***ANOLIS SAGREI* (Brown Anole)**. USA: TEXAS: Angelina Co.: Lufkin, 4211 S Medford Drive (31.3103°N, 94.7202°W; WGS 84). 15 October 2012. Cory Adams. Verified by Toby J. Hibbitts. Biodiversity Research and Teaching Collection, Texas A&M University (TCWC 96833). New county record (Dixon 2013. Amphibians and Reptiles of Texas. 3rd ed., Texas A&M Univ. Press, College Station. 447 pp.). The adult male specimen was collected on a metal plant display in the garden center at The Home Depot in Lufkin, Texas. This was the only individual we observed. The nearest documented record for *A. sagrei* is from Nacogdoches Co. (Saenz et al. 2013. Herpetol. Rev. 44:474), which was collected in the garden center of Lowes in Nacogdoches, Texas. This species has been introduced through the interstate plant trade; however, no individuals have been found outside the initial introduction areas in Texas (Dixon 2013, *op. cit.*). As a result, we agree with Saenz et al. (2013, *op. cit.*) who suggested that the Brown Anoles observed in eastern Texas likely represent new introductions rather than a range expansion of established populations in Texas.

CORY K. ADAMS, **DANIEL SAENZ**, and **JAMES D. CHILDRESS,** Southern Research Station, USDA Forest Service, 506 Hayter St., Nacogdoches, Texas 75965, USA (e-mail: coryadams@fs.fed.us).

***BACHIA GUIANENSIS* (Guyana Bachia)**. COLOMBIA: META: Vista Hermosa, Vereda Madroño, Finca Paimore (2.968804°N, 73.616181°W; datum Bogotá WGS 84). 11 December 2013. Y. R. López Perilla. Colección de Reptiles, Instituto de Ciencias Naturales, Universidad Nacional de Colombia (ICN 12430). Verified by J. E. Carvajal-Cogollo. This lizard was only known from Colombia in the department of Vichada, Corregimiento de Santa Rosa in the Natural National Park El Tuparro (locality Centro Alto Tuparro), department of Guainía in municipality of Inírida and department of Guaviare in the surroundings of San José del Guaviare (Medina-Rangel and Calderon 2013. Herpetol. Rev. 44[3]:474), and Venezuela in the Territorio Federal of the Amazonas state in Río Guapuchi, tributary of Río Ventuari (Hoogmoed and Dixon 1977. Zool. Med. 51:25–31; Gorzula and Señaris 1999. Contribution to the Herpetofauna of the Venezuelan Guayana I: a Data Base. Scientia Guaianae, Caracas, No. 8, 269 pp.; Ávila-Pires 2005. *In* Hollowell and Reynolds [eds.], Checklist of the Terrestrial Vertebrates of the Guiana Shield. Bull. Biol. Soc. Washington 13:25–42; Uetz 2012. TIGR Reptile Database [version Oct 2007]. *In* Bisby et al. [eds.]. Species 2000 and ITIS Catalogue of Life, version 2012. <www.catalogueoflife.org/col/>; Rivas et al. 2012. Zootaxa 3211:1–64). This record extends the range ca. 120 km NW from the nearest known population (San José del Guaviare, Guaviare department, Colombia) (Medina-Rangel and Calderon, *op. cit.*). The extent of distribution to the west near the foothills of the Serranía de la Macarena (ca. 25 km to the foothills of this mountain range) may indicate that this species has a more extensive range than present records suggest, and that it likely occurs throughout the Colombian Guyana shield up to the transition zone of the Amazonian and Andes foothills.

YENY ROCÍO LÓPEZ-PERILLA, Universidad Pedagógica y Tecnológica de Colombia UPTC, Tunja, Boyacá, Colombia (e-mail: yrocio.lopez@gmail.com); **GUIDO F. MEDINA-RANGEL,** Instituto de Ciencias Naturales, Universidad Nacional de Colombia, Apartado Aéreo 7495, Bogotá D.C., Colombia (e-mail: gfmedinar@unal.edu.co); **LUIS EDUARDO ROJAS-MURCIA**, Universidad Pedagógica y Tecnológica de Colombia UPTC, Tunja, Boyacá, Colombia (e-mail: yrocio.lopez@gmail.com).

***DAREVSKIA PONTICA* (Pontic Lizard)**. RUSSIA: KRASNODAR KRAI: Korenovsky District: vicinity of Komsomolsky (45.61644°N, 39.46769°E), 40 m elev. 22 Marh 2014. Slavyansky District: Slavyansk-na-Kubani (45.2646781°N, 38.10118682°E), 5 m elev. 20 April 2014. I. V. Doronin. Verified by N. Ananjeva. These new localities are new extreme northern records for this species (Stugren 1984. *In* W. Böhme [ed.], Handbuch der Reptilien und Amphibien Europas. Band 2/I, Echsen II (Lacerta), pp. 318–331. Aula Verlag, Wiesbaden) that extends the range of this species (sometimes considered a subspecies of *D. praticola*) by 70 km to the north. This record of *D. pontica* comes from Kuban-Azov lowland, where people have destroyed forests in historical times. These populations are synanthropic being found in gardens, orchards, and cemeteries, and often are associated with piles of wood and twigs, similar to their natural habitat (forest litter, fallen trees in the forest). In these habitats, *D. pontica* occurs with *Lacerta agilis*.

IGOR V. DORONIN, Department of Herpetology, Zoological Institute of Russian Academy of Sciences, St. Petersburg 199034, Russia; e-mail: ivdoronin@mail.ru.

***HOLCOSUS LEPTOPHRYS* (Delicate Ameiva)**. REPUBLIC OF PANAMA: VERAGUAS: Cañazas District: San Pablo River (8.29497°N, 81.26454°W; WGS84), 96 m elev. 17 March 2013. V. Bravo and E. E. Flores. Verified by Andreas Hertz. MVUP 2115. This locality helps fill in the distributional gap between populations occurring in extreme southwestern Chiriqui Province, and

those ca. 55 km SE in extreme eastern Veraguas Province (Köhler 2008. Reptiles of Central America, 2nd ed. Herpeton, Verlag Elke Köhler, Offenbach, Germany. 400 pp.). The juvenile lizard was found at night on a sandy riverbank under leaf litter; the presence of adult specimens was confirmed by visual observations along the San Pablo River. This project was conducted under a scientific permit (SE/A-26-13) provided by the Panamanian National Authority for the Environment (ANAM).

ERIC ENRIQUE FLORES, Friends of Santa Fe National Park (AMIPARQUE), and Panama Wildlife Conservation, Apartado 0923-00126, Veraguas, Panama (e-mail: sailax1@gmail.com); **VÍCTOR BRAVO**, University of Panama, School of Biology, Panama City, Panama (e-mail: bravovictor50@yahoo.com); **ANEL RIOS**, Community of Las Trancas, Cañazas District, Veraguas, Panama.

***OPHISAURUS ATTENUATUS* (Slender Glass Lizard)**. USA: FLORIDA: Clay Co.: Middleburg, at Jennings State Forest Headquarters, near the end of Long Horn Road (30.128692°N, 81.964958°W; WGS84; elev. 35 m). 19 November 2013. Elizabeth A. Smith. Verified by Kevin M. Enge. Florida Museum of Natural History (photographic voucher UF-Herpetology 172086). New county record (Krysko et al. 2011. Atlas of Amphibians and Reptiles in Florida. Final report, Project Agreement 08013, Florida Fish and Wildlife Conservation Commission, Tallahassee. 524 pp.). The lizard was found in sandhill habitat. It was first seen on a sidewalk between the two buildings. It then crawled into mulched vegetation and disappeared underground.

BRIAN J. CAMPOSANO (e-mail: brian.camposano@freshfromflorida.com) and **ELIZABETH A. SMITH**, Florida Forest Service, Jennings State Forest, 1337 Long Horn Road, Middleburg, Florida 32068, USA (e-mail: elizabeth.smith@freshfromflorida.com).

***PHRYNOSOMA BRACONNIERI* (Short-tailed Horned Lizard)**. MÉXICO: GUERRERO: Municipality of Olinala: Xixila (17.993334°N, 98.850278°W; WGS84), 1535 m elev. 15 October 2011. Víctor Hugo Jiménez Arcos, Salomón Sanabria Urban, and Eric Centenero Alcalá. Verified by Luis Canseco Márquez. IBH-RF 53. First record for Guerrero, extending the known range of the species ca.70 km SW from Tehuitzingo, Puebla (Garcia-Vazquez et al. 2005. Publ. Soc. Herpetol. Mex. 1:152–169). The lizard was found active on the ground in oak forest.

VÍCTOR H. JIMÉNEZ-ARCOS, Laboratorio de Ecología, Unidad de Biotecnología y Prototipos, FES Iztacala, Universidad Nacional Autónoma de México, Av. De los Barios S/N, Los Reyes Ixtacala, Tlalnepantla, México, C.P. 54090 (e-mail: biol.victor.jimenez@gmail.com); **ERIC CENTENERO-ALCALÁ** and **EDMUNDO PEREZ-RAMOS,** Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autónoma de México, A.P. 70-399, México; **SAMUEL A. SANTA CRUZ-PADILLA**, Naturam Sequi A.C. 16 de Septiembre #43, Col. Cd. de los Niños, Naucalpan de Juárez, Edo. de México C.P. 53450.

***PHYLLODACTYLUS DAVISI* (Davis's Leaf-toed Gecko)**. MÉXICO: COLIMA: Municipality of Manzanillo: Hwy 200 from Manzanillo to Cihuatlán (19.1366°N, 104.3382°W; WGS84), 41 m elev. 20 September 2006. F. R. Méndez-de la Cruz, A. H. Díaz de la Vega-Pérez, and R. A. Lara-Resendiz. Verified by Christopher Blair. ROM 46394–46396. First report of this species since it was described by Dixon (1964. New Mexico State Univ. Res. Cent. Sci. Bull. 61-1: i–iv, 1–139), who considered the species as occurring in coastal lowlands of Colima and Michoacán, and removed it from *P. lanei* as treated in part by Duellman (1958. Occ. Pap. Mus. Zool. Univ. Michigan [589]:1–22). Murphy et al. (2009. S. Am. J. Herpetol. 4:17–24) recognized *P. davisi*, but added no new information on its distribution. The new record reported herein indicates that more searches for this species are needed from within its purported range (Dixon 1964, *op. cit.*) to assess its present distribution. Collections were made under a permit issued by SEMARNAT (# 03489/07).

FAUSTO R. MÉNDEZ-DE LA CRUZ, Laboratorio de Herpetología, Departamento de Zoología, Instituto de Biología, Universidad Nacional Autónoma de México, AP 70515, CP 04510, México, D.F. ***MICRURUS FULVIUS* (Harlequin Coralsnake)**. USA: FLORIDA: Hamilton Co.: Twin Rivers State Forest, Blue Spring Longleaf tract, ~2.07 km NE of jct of CR-6 and CR-143 (30.5013°N, 83.2067°W; WGS 84). 9 March 1994. Dale R. Jackson and Cathleen NeSmith. Verified by Kenneth L. Krysko. UF 172491 (2 digital photographic vouchers). New county record (Krysko et al. 2011. Atlas of Amphibians and Reptiles in Florida. Florida Fish and Wildlife Conservation Commission, Tallahassee. 524 pp.).

A juvenile coral snake ~24 cm SVL was captured beneath a log in a high quality upland pine forest that is regularly managed with prescribed fire to limit hardwood encroachment. Although the species occurs statewide, this is one of five counties for which no previous record exists although specimens are known from adjacent counties just across the Suwannee (UF 120515, 12.2 km SSE, Suwannee Co.) and Withlacoochee (LSUMZ 82096, 11.7 km NNW, Madison Co.) rivers.

The 799-ha Blue Spring Longleaf tract was acquired by the state of Florida in 1993 and added to Twin Rivers State Forest to protect one of the premier examples of upland pine forest in the state.

We thank Kenneth Krysko for providing distance estimates of nearest known specimens taken from Krysko et al. (2011, *op. cit.*).

DALE R. JACKSON (e-mail: drjackson@admin.fsu.edu) and **CATHLEEN NESMITH**, Florida Natural Areas Inventory, Florida State University, 1018 Thomasville Road, Ste. 200-C, Tallahassee, Florida 32303, USA.

***NERODIA SIPEDON* (Common Watersnake)**. USA: ILLINOIS: Lee Co.: Nachusa Grasslands, 5.9 km NW Franklin Grove (41.891657°N, 89.379020°W; WGS 84). 13 September 2010. T. G. Anton and P. W. Willink. Verified by Chris Phillips. Illinois Natural History Survey (INHS 23596; shed skin fragments). New county record (Phillips et al. 1999. Field Guide to Amphibians and Reptiles of Illinois. Illinois Natural History Survey, Urbana, Illinois. 282 pp.). Shed skin found in Franklin Creek in Tellabs Savanna Unit during fish survey. The species is documented from adjacent Ogle Co., where an individual was observed at the Flagg Rd. bridge crossing Clear Creek in Ogle County on 21 June.

The 2013 Herpetofaunal Survey was funded by a grant from The Friends of Nachusa Grasslands with access and support provided by The Nature Conservancy.

Notable Records of Amphibians and Reptiles from Colima, Nayarit, Jalisco, and Zacatecas, México

We conducted herpetofaunal field surveys in the western Mexican states of Colima, Jalisco, Nayarit, and Zacatecas from 21 June 2008 through 7 October 2012. Our efforts were focused on areas where little or no previous sampling had been done. During that time we visited seven different areas, including lower elevations of Volcán de Colima (Colima); the Tepalcatepec Valley, Sierra del Alo, Sierra de los Huicholes, Sierra Quila and Sierra del Tigre (Jalisco); Mesa del Nayar and Sierra Pajaritos (Nayarit); and near Santa Catarina (Zacatecas). All geographic coordinates were taken with a Garmin Etrex Legend Hcx, using datum WGS84. Photographic vouchers were deposited in the digital collection of The University of Texas at Arlington (UTADC). In some instances, more than one specimen was found at different localities within a municipality. Those are identified in the species accounts with UTADC numbers; full locality information for them can be acquired from records in The University of Texas at Arlington (UTA) collections database. Because some of the species are under phylogenetic review, we will mention in those accounts which geographic population variant (e.g., subspecies) our samples would have been referred to in previous literature; some of those populations will most likely be elevated to full species in the near future. All specimens were verified by Eric N. Smith and/or Luis Canseco-Marquez. Common names in English were taken from Liner and Casas-Andreu (2008).

CAUDATA — SALAMANDERS

***AMBYSTOMA ROSACEUM* (Tarahumara Salamander).** JALISCO: Municipality of Bolaños: Sierra de los Huicholes, 29 km NW of Bolaños on road to Huejuquilla (21.897844°N, 103.860368°W), 2440 m elev. 14 September 2011. I. Ahumada-Carrillo and M. A. Iñiguez. UTADC 7518, 7575. First record for Jalisco; the closest known locality for this species is ca. 60 airline km WSW in the Sierra de Alica, Nayarit (Canseco-Márquez et al. 2007). The salamander was found in a permanent stream in pine-oak forest. Shaffer et al. (2013) state that it occurs in Jalisco, but do not reference any specific locality. The geographic population variant the specimen would have been referred to in the past was *A. r. nigrum*.

***PSEUDOEURYCEA BELLI* (Bell's False Brook Salamander).** JALISCO: Municipality of Bolaños: Sierra de los Huicholes, 29 km NW of Bolaños on road to Huejuquilla (21.897917°N, 103.860525°W), 2445 m elev. 14 September 2011. I. Ahumada-Carrillo. UTADC 7632. First municipality record and an extension of its known range ca. 75 km W from the closest known locality, 0.8 km N of Mesa de la Virgen, Sierra Morones, Zacatecas (Wilson and McCraine 1979). The salamander was found in pine-oak forest. Another sample of this species (UTADC 7503) was recorded from an additional locality within the municipality; full locality information can be assessed from the UTA collections database. The geographic population variant the specimen would have been referred to in the past was *P. b. belli*.

ANURA — FROGS

***CRAUGASTOR AUGUSTI* (Barking Frog).** JALISCO: Municipality of Mezquitic: Sierra de los Huicholes, 85.5 km NW of Bolaños on road to Huejuquilla (22.305712°N, 103.931551°W), 2150 m elev. 14 September 2011. I. Ahumada-Carrillo. UTADC 7515. First municipality record, extending the known range in Jalisco ca. 61 km NW from the closest known locality at La Laguna (= Laguna Grande) (Zweifel 1956). The frog was found under a rock in oak forest. Two additional samples were recorded from localities within the municipality (UTADC 7495, 7497); full locality information can be accessed from UTA collections database. The geographic population variant the specimen would have been referred to in the past was *C. a. cactorum*.

***ELEUTHERODACTYLUS NIVICOLIMAE* (Nevado de Colima Chirping Frog).** JALISCO: Municipality of Tecalitlán: 16 km SE of Tecalitlán on road to Jilotlán de los Dolores (19.448328°N, 103.226213°W), 1635 m elev. 25 July 2011. C. Grünwald and I. Ahumada-Carrillo. UTADC 7635. Municipality of Concepcion de Buenos Aires: 1.2 km E (by trail) of 5.5 km S (by road) of La Manzanilla de la Paz, on road to Concepcion de Buenos Aires (19.965875°N, 103.194664°W), 2115 m elev. 21 August 2010. I. Ahumada-Carrillo. UTADC 7633, 7634. Only the fourth and fifth reported records for this species, and first municipality records that extend the range in Jalisco, respectively, 33 airline km SE of El Floripondio, Nevado de Colima, Municipality of San Gabriel (Lynch 1970) and 37 airline km NW of 21 km SE of Mazamitla, Municipality of Quitupan (Reyes-Velasco et al. 2012). Both specimens were found calling on understory plants in Pine-oak forest. While a black and white photograph was given in the description of this species, the one included herein is the first published color image of this species in the literature (Fig. 1).

***INCILIUS PERPLEXUS* (Confusing Toad).** JALISCO: Municipality of Jilotlán de los Dolores: 7.7 km NW of Tepalcatepec, Michoacán

PHOTO BY IVAN TRINIDAD AHUMADA-CARRILLO

FIG. 1. *Eleutherodactylus nivicolimae* 16 km SE of Tecalitlán on road to Jilotlán de los Dolores, Jalisco, México (UTADC 7635).

PHOTO BY CHRISTOPH I. GRÜNWALD

FIG. 2. *Incilius perplexus* from 7.7 km NW of Tepalcatepec, Michoacán, México (UTADC 7509).

(19.251069°N, 102.866913°W), 498 m elev. 24 July 2011. C. Grünwald and I. Ahumada-Carrillo. UTADC 7509. First record for Jalisco, extending the known range 53 airline km W of the closest known locality at Apatzingán, Michoacán (Duellman 1961). The toad was found AOR in tropical deciduous forest. Although this species appears to be widespread in the "Tierra Caliente" region of Jalisco, Michoacán, Guerrero, Estado de México, Morelos, and Puebla, there exist no published photographs of this species, thus we include one of the voucher specimen (Fig. 2).

***LEPTODACTYLUS FRAGILIS* (Mexican White-lipped Frog).** JALISCO: MUNICIPALITY OF PIHUAMO: 1.5 km S of Puente de Fatima (19.132729°N, 103.386994°W), 430 m elev. 29 July 2012. C. Grünwald and I. Ahumada-Carrillo. UTADC 7622. First record from Jalisco, which fills a gap in the known distribution of this species between northeastern Colima and western Michoacán (Heyer et al. 2006). The frog was found calling in a flooded field surrounded by tropical deciduous forest.

***LITHOBATES NEOVOLCANICUS* (Transverse Volcanic Leopard Frog).** JALISCO: MUNICIPALITY OF BOLAÑOS: Sierra de los Huicholes, 13.5 km W of Bolaños, on road to Huejuquilla (21.87503°N, 103.81775°W), 1580 m elev. 13 May 2011. I. Ahumada-Carrillo. UTADC 7507. First record for the municipality, extending the range 41 airline km WNW from Cerrito Pelón, Atolinga, Zacatecas (Ahumada-Carrillo et al. 2011). The frog was found in an earthen cattle tank surrounded by oak forest.

***SMILISCA FODIENS* (Lowland Burrowing Treefrog).** JALISCO: MUNICIPALITY OF BOLAÑOS: Sierra de los Huicholes, 13.8 km W of Bolaños, on road to Huejuquilla (21.875403N, 103.819072°W), 1600 m elev. 20 June 2012. I. Ahumada-Carrillo. UTADC 7619. First municipality record that also fills a northern distributional gap between localities in Nayarit (Duellman 2001) and Municipality of Trinidad García de la Cadena, Zacatecas (Ahumada-Carrillo et al. 2011).

SQUAMATA — LIZARDS

***ELGARIA KINGII* (Madrean Alligator Lizard).** JALISCO: MUNICIPALITY OF MEZQUITIC: Sierra de los Huicholes, 88.9 km NW of Bolaños, on road to Huejuquilla (22.315394°N, 103.930005°W), 2075 m elev. 4 October 2011. I. Ahumada-Carrillo. UTADC 7496. First municipality record, and first for this species in the Sierra de los Huicholes, extending the known range ca. 70 km NW from Atolinga, Zacatecas (Ahumada-Carrillo 2010). The lizard was found active on leaf litter in oak forest. The geographic population variant this specimen would have been referred in the past was *E. k. ferruginea*.

***CTENOSAURA CLARKI* (Michoacán Club Tail).** JALISCO: MUNICIPALITY OF JILOTLÁN DE LOS DOLORES: Corongoros (south shore of Presa Constitución de Apatzingán), 10 km NNE of Tepalcatepec, Michoacán (19.265664°N, 102.793933°W), 420 m elev. 24 July 2011. C. Grünwald and I. Ahumada-Carrillo. UTADC 7510, 7511. First record from Jalisco; the closest known locality is 9.2 km SSW at Tepalcatepec, Michoacán (Duellman 1961). Numerous other individuals were observed within tropical deciduous forest in hollowed-out tree trunks that were being used as fence posts.

***HELODERMA HORRIDUM* (Beaded Lizard).** JALISCO: MUNICIPALITY OF BOLAÑOS: Sierra de los Huicholes, 4 km W of Bolaños, on road to Huejuquilla (21.838889°N, 103.805111°W), 1095 m elev. 19 July 2011. I. Ahumada-Carrillo. UTADC 7494, 7523, 7524. First municipality record, extending the known range ca. 95 airline km SW from the closest known locality, a dirt road between San Juan Capistrano, Zacatecas, and San Rafael de las Tablas, Durango (Avila-Villegas 2007). The lizard was found DOR in tropical deciduous forest. Reiserer et al. (2013) elevated all subspecies of *H. horridum* to full species, and discussed the uselessness of using subspecies designations in modern phylogenetic taxonomy. The geographic population variant the specimen would have been referred to in the past was *H. h. horridum*.

***SCELOPORUS SHANNONORUM* (Shannon's Spiny Lizard).** ZACATECAS: MUNICIPALITY OF VALPARAISO: 8 km NE of Santa Catarina (22.211831°N, 103.872749°W), 2370 m elev. 14 September 2011. I. Ahumada-Carrillo. UTADC 7587. First record for Zacatecas; the closest known locality is ca. 32 airline km S at Rancho la Berberia, Jalisco (Smith et al. 2006). The lizard was found in pine forest.

SQUAMATA — SNAKES

***ADELOPHIS COPEI* (Cope's Mountain Meadow Snake).** JALISCO: MUNICIPALITY OF TECOLOTLÁN: Sierra de Quila, 5 km NW Quila el

Grande (20.375999° N, 14.112879°W), 1876 m elev. 7 October 2012. I. Ahumada-Carrillo. UTADC 7623. First municipality record that fills a large range gap in Jalisco between La Quemada (Municipality of Magdalena) to the north and 8.7 miles (13.9 km) E of Tapalpa (Municipality of Tapalpa) to the south. (Taylor 1942; Rossman and Blaney 1968). The snake was found under a rock near a permanent stream in an ecotone between oak forest and grassland.

***GEOPHIS DUGESI* (Duge's Earth Snake)**. JALISCO: Municipality of Bolaños: Sierra de los Huicholes, 29 km NW of Bolaños, on road to Huejuquilla (21.898278°N, 103.859972°W), 2430 m elev. 21 June 2008.R. Mederoz, J. Padilla and I. Ahumada-Carrillo. UTADC 7520, 7521. First record for the municipality, extending the range 126 airline km WNW from the closest known locality, on Sierra del Laurel, Municipality of Villa Hidalgo, Jalisco (Rodriguez and Vázquez 1994). The snake was found under a rock in pine-oak forest. The geographic population variant the specimen would have been referred to in the past was *G. d. aquilonaris*.

***GEOPHIS SIEBOLDI* (Siebold's Earth Snake)**. COLIMA: Municipality of Villa de Alvarez: 7 km N of turn off to El Chivato, on Chiapa–Montitlán road (19.393047°N, 103.672008°W), 1320 m elev. 11 July 2012. J. Reyes-Velasco. UTADC 7629, 7631. First record for Colima, extending the known range of the species 18.5 km W from an unpublished record (KU 129232) at 19.8 km S of Tecalitlán, Jalisco (KU 129232). The snake was found AOR at night in a sugarcane field surrounded by secondary vegetation. JALISCO: Municipality of Tecalitlán: 16 km SE of Tecalitlán on road to Jilotlán de los Dolores (19.448328°N, 103.226213°W), 1635 m elev. 25 July 2012. C. Grünwald and I. Ahumada-Carrillo. UTADC 7626–7628. First published record for this species in Jalisco, which is located ca. 17 km E of an unpublished record (KU 129232) from 19.8 km S of Tecalitlán, Jalisco. The snake was found DOR in pine forest. The original holotype and syntypes of this species were lost or destroyed during World War II (Downs 1957). Since the original description, this species is known from only eight specimens, one from Coalcomán, Michoacán (UMMZ 104698), one from Amula, Guerrero (BMNH 90.4.24.12), the aforementioned unpublished record from Jalisco (KU 129232), and five specimens without specific locality data (Zoologisches Museum, Berlin; ZMB 1555–1559). Aside from extending the known range, our localities constitute the first recent records for this species, and the photograph (Fig. 3) is the initial one to appear in the literature.

PHOTO BY JACOBO REYES VELASCO

Fig. 3. *Geophis sieboldi* from 7 km N of turnoff to El Chivato on Chiapa-Montitlán road. Colima, México (UTADC 7629, 7631).

***LAMPROPELTIS MEXICANA* (San Luis Potosí Kingsnake)**. JALISCO: Municipality of Bolaños: Sierra de los Huicholes, El Astillero, 27 km NW of Bolaños on road to Huejuquilla (21.888062°N, 103.855821°W), 2300 m elev. 22 June 2010. R. Mederoz. UTADC 7519. First municipality record. Municipality of Mezquitic: 2.2 airline km SE of Bajío las Gallinas (22.042667°N, 103.894444°W), 2446 m elev. 28 July 2011. J. Jones, I. Ahumada-Carrillo, C. Grünwald, and J. Reyes-Velasco. UTADC 7501. First municipality record. Both sites fill a distributional gap for the species between locations west of Atolinga, Zacatecas (Ahumada-Carrillo et al. 2011), and Mesa del Nayar–Santa Teresa Hwy, Nayarit (Hansen et al. 2011). The first snake was found DOR in pine-oak forest; the second one was crossing a paved road at night in pine forest. Two additional samples (UTADC 7512, 7516) were recorded from localities within the Municipality of Mezquitic; full locality information can be accessed from the UTA collections database. The geographic population variant that all mentioned specimens would have been referred to in the past was *L. m. greeri*.

***LEPTODEIRA SPLENDIDA* (Splendid Cat-eyed Snake)**. JALISCO: Municipality of Bolaños: Bolaños (21.83576°N, 103.777757°W), 892 m elev. 20 June 2012. I. Ahumada-Carrillo. UTADC 7618. First municipality record, extending the range of the species 80 airline km NW of the closest known locality at Mezquital del Oro, Zacatecas (Ahumada et al. 2011). The snake was found AOR in tropical deciduous forest. The geographic population variant the specimen would have been referred to in the past was *L. s. bressoni*.

***LEPTOPHIS DIPLOTROPIS* (Pacific Coast Parrot Snake)**. JALISCO: Municipality of Villa Guerrero: 9 km SW Villa Guerrero (21.959250°N, 103.684500°W), 1924 m elev. 25 October 2011. I. Ahumada-Carrillo. UTADC 7588, 7589. First municipality record and northernmost record in Jalisco, extending the known range ca. 140 airline km N from the closest known localities near Zapopan, Jalisco (Reyna-Bustos et al. 2007). The snake was found DOR in tropical deciduous forest. The geographic population variant the specimen would have been referred to in the past was *L. d. diplotropis*.

***MASTIGODRYAS CLIFTONI* (Clifton's Lizard Eater)**. JALISCO: Municipality of Bolaños: Sierra de los Huicholes, Sierra Los Huicholes, 22.4 km NW of Bolaños, on road to Huejuquilla (21.886000°N, 103.845389°W), 2080 m elev. 20 July 2010. I. Ahumada-Carrillo and J. Padilla. UTADC 7522. First municipality record and first for the Sierra de los Huicholes. The closest known localities are 93 airline km SW at Laguna de Santa Maria del Oro, Nayarit, and ca. 140 km SE in the Barranca de Oblatos-Huentitan, Jalisco (Ponce-Campos and Huerta-Ortega 1998). The snake was found in pine-oak forest. NAYARIT: Municipality of El Nayar: near El Maguey, El Venado – Mesa de Nayar Hwy (22.145892°N, 104.752247°W), 1750 m elev. 14 August 2010. C. Grünwald and C. Rodriguez. UTADC 7586. This record fills a gap in the distribution of the species, between Plomosas, Sinaloa, 127 km N, and Laguna de Santa Maria del Oro, 87 km S (Hardy and McDiarmid 1969; Ponce-Campos and Huerta-Ortega 1998). The snake was found during a foggy morning while crossing the highway in oak forest.

PHOTO BY CHRISTOPH I. GRÜNWALD

FIG. 4. *Rena bressoni* from 17 km NW of Tepalcatepec, Michoacán, Mexico (UTADC 7513).

***MICRURUS DISTANS* (West Mexican Coralsnake).** NAYARIT: MUNICIPALITY OF LA YESCA: Sierra Pajaritos, 5.7 airline km NW of La Yesca (21.352639°N, 104.052194°W), 2369 m elev. 28 August 2010. I. Ahumada Carrillo, C. Grünwald and J. Jones. UTADC 7571. First municipality record, first record for the Sierra Pajaritos, and by far the highest recorded elevation reported for this species (Roze 1996). The closest known records are from 40 airline km E at Magdalena, Jalisco, and 50 km W at Laguna de Santa Maria del Oro, Nayarit (Roze 1996). The snake was found in pine-oak forest. JALISCO: MUNICIPALITY OF CAÑADAS DE OBREGON: Presa EL Zapotillo, 17 km W Cañadas de Obregon (21.139630°N, 102.806214°W), 1708 m elev. 9 July 2012. I. Ahumada-Carrillo and J. Orozco. UTADC 7625. First municipality record, extending the range ca. 53 airline km SE from Mezquital del Oro, Zacatecas (Ahumada-Carrillo and Vazquez-Huizar 2012). The snake was found in tropical deciduous forest. The geographic population variant all specimens would have been referred to in the past was *M. d. zweifeli.*

***THAMNOPHIS ERRANS* (Mexican Wandering Gartersnake).** JALISCO: MUNICIPALITY OF MEZQUITIC: Sierra de los Huicholes, Bajío Las Gallinas (22.056736°N, 103.906512°W), 2560 m elev. 29 July 2011. C. Grünwald, J. Jones, I. Ahumada-Carrillo, and J. Reyes-Velasco. UTADC 7572. First record for Jalisco, extending the known range of the species 70 airline km S from the closest known locality at Valparaiso, Zacatecas (Rossman et al. 1996). The snake was found in pine forest.

***THAMNOPHIS PULCHRILATUS* (Mexican Highland Gartersnake).** JALISCO: Municipality of Mezquitic: Sierra de los Huicholes, Bajío Los Amoles (22.060218°N, 103.930936°W), 2480 m elev. 5 July 2011. I. Ahumada-Carrillo. UTADC 7508. First municipality record, and first for the Sierra de los Huicholes. The closest known localities are 101 airline km W at Santa Teresa, Nayarit, and 50 km SE at Atolinga, Zacatecas (Ahumada-Carrillo 2010). The snake was found in a bunch grass meadow surrounded by pine-oak forest.

***RENA BRESSONI* (Michoacán Slender Threadsnake).** JALISCO: Municipality of Jilotlán de los Dolores: 17 km NW of Tepalcatepec, Michoacán (19.307670°N, 102.909775°W), 630 m elev. 24 July 2011. C. Grünwald and I. Ahumada-Carrillo. UTADC 7513, 7514. First record for Jalisco, extending the range 96 airline km W from the closest known locality at Hacienda El Sabino, SW of Uruapan, Michoacán (Duellman 1961). The snake was found AOR in tropical deciduous forest. This species appears to be known only from the type specimen and possibly one lost sample from Aguililla, Michoacán (Duellman 1961), and we include the first photograph of this species to be published in the literature (Fig. 4).

Acknowledgments.—We thank Chris Rodriguez, Mario Alberto Iñiguez, Jesús Orozco, and Rafael Mederos for their valuable assistance in the field.

First Departmental Records of Amphibians and Reptiles from Intibucá, Lempira, and Ocotepeque in Southwestern Honduras

McCranie (2007, 2011) demonstrated that the departments of Intibucá, Lempira, and Ocotepeque in southwestern Honduras were among the most understudied departments in the entire country in respect to their amphibian and snake faunas; the same holds true for the lizards and turtles in those three departments (McCranie, *in prep.*). On 24 November 2011 and from 14 to 20 June 2012, first departmental records for 20 species were documented from various localities, resulting in one for Intibucá, 10 for Lempira, and nine for Ocotepeque. All samples were collected by J. R. McCranie. John C. Murphy verified the identification of the FMNH specimens, except for *Incilius valliceps* and *Holcosus undulatus*, which were verified by Alan Resetar; Steve W. Gotte verified the USNM specimen. Coordinates for all localities were taken with a GPS device using map datum WGS84. Ecological life zone vegetation formations used herein (placed in parentheses) are those classified by Holdridge (1967); others refer to specific vegetation associations at collecting sites.

ANURA — FROGS

Lempira

***INCILIUS VALLICEPS* (Southern Gulf Coast Toad; Sapo Común de Crestas Grandes)**. Near pond just S of Gracias (14.566847°N, 88.583409°W), 860 m elev. 19 June 2012. FMNH 283705. Closest known locality for this species is ca. 25 km NW at a site 8 km SE of Santa Rosa de Copán, Copán (McCranie 2006). The toad was active on the ground at night in a pasture adjacent to the pond in denuded pine-oak forest (Premontane Moist Forest).

***DENDROPSOPHUS MICROCEPHALUS* (Small-headed Treefrog; Ranita Trepadora Amarilla)**. Pond just S of Gracias (14.566847°N, 88.583409°W), 860 m elev. 19 June 2012. FMNH 283723–27. Closest known locality for this species is ca. 25 km NW at a site 8 km SE of Santa Rosa de Copán, Copán (McCranie 2006). Two males were calling at night on water hyacinths (*Eichhornia crassipes*) floating on surface of the pond surrounded by pasture in denuded pine-oak forest (Premontane Moist Forest).

JAMES R. McCRANIE
10770 SW 164TH Street, Miami, Florida 33157-2933, USA
e-mail: jrmccrani@bellsouth.net

***SCINAX STAUFFERI* (Stauffer's Long-nosed Treefrog; Ranita Trepadora Nariguda)**. Pond just S of Gracias (14.566847°N, 88.583409°W), 860 m elev. 19 June 2012. FMNH 283743–44. Closest known locality for this species is ca. 25 km NW at a site 8 km SE of Santa Rosa de Copán, Copán (McCranie 2006). This species is now known from all 18 Honduran departments. Numerous males were calling at night from emerging grass stalks in flooded areas adjacent to the pond surrounded by pasture in denuded pine-oak forest (Premontane Moist Forest).

***SMILISCA BAUDINII* (Mexican Treefrog; Rana Trepadora Común)**. Near pond just S of Gracias (14.566847°N, 88.583409°W), 860 m elev. 19 June 2012. FMNH 283745–47. Closest known locality for this species is ca. 27 km NW at a site 6.4 km SE of Santa Rosa de Copán, Copán (McCranie 2006). This species is now known from all 18 Honduran departments. Males were calling at night from small isolated trees and on the ground in a pasture adjacent to the pond in denuded pine-oak forest (Premontane Moist Forest).

***LEPTODACTYLUS MELANONOTUS* (Sabinal Frog; Ranita de Charco de Dos Espinas)**. Near pond just S of Gracias (14.566847°N, 88.583409°W), 860 m elev. 19 June 2012. FMNH 283720–22, 283749. Closest known locality for this species is ca. 75 km NW at Copán, Copán (McCranie 2006). Males were calling at night from inside grass clumps in flooded pasture adjacent to the pond in denuded pine-oak forest (Premontane Moist Forest).

***HYPOPACHUS VARIOLOSUS* (Sheep Frog; Ranita Oveja Común)**. Near pond just S of Gracias (14.566847°N, 88.583409°W), 860 m elev. 19 June 2012. FMNH 283728–29. Closest known locality for this species is ca. 25 km NW at a site 8 km SE of Santa Rosa de Copán, Copán (McCranie 2006). Males were calling at night from burrows below grass clumps in and around flooded pasture adjacent to the pond surrounded by denuded pine-oak forest (Premontane Moist Forest).

***LITHOBATES BROWNORUM* COMPLEX (Brown's Leopard Frog; Rana de Charco Manchada)**. Pond just S of Gracias (14.566847°N, 88.583409°W), 860 m elev. FMNH 283733. Closest known locality for members of this species complex is ca. 25 km NW at 8 km SE of Santa Rosa de Copán, Copán (McCranie 2006). The frog was active at night in shallow water at edge of pond. This species complex is now known from all 18 Honduran departments. The Lempira population appears to represent an undescribed species related to *L. brownorum* and *L. forreri* as discussed by McCranie and Castañeda (2007).

Ocotepeque

***LEPTODACTYLUS MELANONOTUS* (Sabinal Frog; Ranita de Charco de Dos Espinas)**. Near Río Lempa at Antigua (14.40009°N, 89.200067°W), 725 m elev. 17 June 2012. FMNH 283718–19. Closest known locality for this species is ca. 8 km S at San Ignacio, Chalatenango, El Salvador (Köhler et al. 2005); the closest known Honduran locality is ca. 55 km N at Copán, Copán (McCranie 2006). Males were calling at night on ground in and adjacent to inundated areas in denuded dry forest converted to pastures (Premontane Dry Forest).

SQUAMATA — LIZARDS

Intibucá

***SCINCELLA CHERRIEI* (Brown Forest Skink; Eslaboncillo Pardo)**. Near La Rodadora. (14.500248°N, 88.116708°W), 1600 m elev. 24 November 2011. USNM 580447. Closest known locality for this species is ca. 35 km NE at Siguatepeque, Comayagua, Honduras (UF 124825). The skink was under a log during the day in a coffee grove carved from broadleaf forest mixed with pine-oak forest (Lower Montane Moist Forest).

Lempira

***HEMIDACTYLUS FRENATUS* (Common House Gecko; Besucona)**. Hotel Finca El Capitán, Gracias (14.566901°N, 88.583448°W), 855 m elev. 20 June 2012. FMNH 283709–11. Closest known locality for this species is ca. 75 km NW at Copán, Copán, Honduras (FMNH 282557–59). The gecko was active at night on the hotel walls.

***SCINCELLA CHERRIEI* (Brown Forest Skink; Eslaboncillo Pardo)**. Villa Verde. (14.550237°N, 88.616669°W), 1105 m elev. 20 June 2012. FMNH 283734. Closest known locality for this species is ca. 55 km ESE at La Rodadora, Intibucá, Honduras (see *S. cherriei* note above). The lizard was under a rock during the day in second growth pine-oak forest (Premontane Moist Forest).

Ocotepeque

***COLEONYX MITRATUS* (Tropical Banded Gecko)**. Between Antigua and Río Lempa (14.40009°N, 89.200064°W), 730 m elev. 17 June 2012. FMNH 283716. Closest known locality for this species is ca. 35 km SW at Lago de Güija, Santa Ana, El Salvador (Köhler et al. 2005); closest known Honduran locality is ca. 150 km NE at Lago de Yojoa, Cortés (UF 11626). The gecko was under a rock during the day within a pasture transformed from dry forest (Premontane Dry Forest).

***HEMIDACTYLUS FRENATUS* (Common House Gecko; Besucona)**. Nuevo Ocotepeque (14.43348°N, 89.683353°W), 835 m elev. 16 June 2012. FMNH 283707–08. Closest known locality for this species is ca. 55 km N at Copán, Copán, Honduras (FMNH 282557–59, UF 166346). These lizards were active at night on walls of a hotel surrounded by denuded dry forest (Premontane Dry Forest).

***SCINCELLA INCERTA* (Stuart's Forest Skink; Eslaboncillo de Hojarasca)**. Las Hojas (14.450173°N, 89.283431°W), 1600 m elev. 15 June 2012. FMNH 283730–32. Closest known locality is ca. 150 km NNE at La Fortuna Camp, Santa Bárbara, Honduras (Townsend 2005). The skinks were under pine needles during the day in second growth pine forest mixed with broadleaf forest (Lower Montane Moist Forest).

***HOLCOSUS UNDULATUS* (Rainbow Ameiva; Largartija Metálica)**. Near Río Lempa at Antigua (14.40009°N, 89.200067°W), 725 m elev. 17 June 2012. FMNH 283706. Closest known locality for this species is ca. 5 km S at Citalá, Chalatenango, El Salvador (Köhler et al. 2005); closest known Honduran locality is ca. 55 km N near Copán, Copán (USNM 563572). The lizard was active during a sunny period on rock wall in a pasture transformed from dry forest (Premontane Dry Forest).

SQUAMATA — SNAKES

Lempira

***NINIA DIADEMATA* (Ring-necked Coffee Snake; Dormilona de Collar)**. Bonilla. (14.566705°N, 88.583459°W), 900 m elev. 19 June 2012. FMNH 283717. Closest known locality for this species is ca. 65 km NW at Río Amarillo, Copán, Honduras (McCranie 2011). The snake was under a rock during the day adjacent to a rock wall in second growth pine-oak forest (Premontane Moist Forest).

Ocotepeque

***EPICTIA ATER* (Threadsnake; Culebra Lombriz)**. Near Río Lempa at Antigua (14.40009°N, 89.200067°W), 725 m elev. 17 June 2012. FMNH 283735–37; between Antigua and Río Lempa (14.40009°N, 89.200064°W), 730 m elev. 18 June 2012. FMNH 283738–40. Closest known locality for this species is ca. 35 km WSW at 6 km S of Metapán, Santa Ana, El Salvador (Köhler et al. 2005); closest known Honduran locality is ca. 55 km N at Copán, Copán (McCranie 2011). The snakes were under rocks in pastures altered from dry forest (Premontane Dry Forest).

***INDOTYPHLOPS BRAMINUS* (Brahminy Blindsnake; Culebrilla Ciega)**. Near Río Lempa at Antigua (14.40009°N, 89.200067°W), 725 m elev. 17 June 2012. FMNH 283712–14. Between Antigua and Río Lempa (14.40009°N, 89.200064°W), 730 m elev. 18 June 2012. FMNH 283715. Closest reported locality for this introduced blindsnake is ca. 95 km S at San Salvador, San Salvador, El Salvador (Köhler et al. 2005); closest known Honduran locality is ca. 120 km NE near San José de Colinas, Santa Bárbara (McCranie 2011). The snakes were under rocks in pastures converted from dry forest (Premontane Dry Forest), one of which (FMNH 283715) was under the same rock and in direct contact in a "ball" with three *Epictia ater* (FMNH 283738–40).

TESTUDINES — TURTLES

Ocotepeque

***RHINOCLEMMYS PULCHERRIMA* (Painted Wood Turtle; Casco Rojo)**. Near Río Lempa at Antigua (14.40009°N, 89.200067°W), 725

m elev. 17 June 2012. FMNH 283551. Between Nueva Ocotepeque and Antigua (14.416736°N, 89.183476°W), 800 m elev. 18 June 2012. FMNH 283550. Closest known locality for this species is ca. 28 km SW near Metapán, Santa Ana, El Salvador (Köhler et al. 2005); closest known Honduran locality is ca. 50 km N at Copán, Copán (UNAH 425; also *R. pulcherrima* not previously reported from Department of Copán). The Antigua specimen (FMNH 283551) was foraging during afternoon on small plants and shrubs located adjacent to a diminutive muddy temporary pond within a pasture transformed from dry forest (Premontane Dry Forest). The other specimen (FMNH 283550) was crossing during morning hours, a highway passing through badly disturbed dry forest (Premontane Dry Forest). Of three others from the Río Lempa locality that were not collected, two were feeding on human feces during the afternoon and the other was active at night in a small temporary pond.

***KINOSTERNON SCORPIOIDES* (Scorpion Mud Turtle; Tortuga Escorpión)**. Near Río Lempa at Antigua (14.4009°N, 89.89.200067°W), 725 m elev. 17 June 2012. FMNH 283748. Closest known locality for this species is ca. 28 km SW near Metapán, Santa Ana, El Salvador (Köhler et al. 2005); closest known Honduran locality is ca. 60 km NE at a site NW of Gracias, Lempira (Meyer and Wilson, 1973). Numerous adults and hatchlings were active at night in and around several small temporary ponds in pastures converted from dry forest (Premontane Dry Forest).

Acknowledgments.—Collecting (Resolución DE-MP–102–2012) and export (Constancia 036–2012–DVS-ICF; Constancia 038–2012–DVS-ICF) permits were issued by Iris Acosta and Said Laínez of the Instituto Nacional de Conservación y Desarrollo Forestal, Áreas Protegidas y Vida Silvestre (ICF) Tegucigalpa. Leonardo Valdés Orellana was instrumental in acquiring permits, copies of which are on file at FMNH and USNM. Partial support for the 2012 fieldwork was provided by the Marshall Field Fund, FMNH.

With 165 recognized amphibian and reptile species, Alabama possesses some of the highest herpetofaunal diversity in North America. This species diversity is due in part to the seven recognized geographic provinces that comprise the state. Many of the records we report here are primarily from Lawrence and Winston counties (i.e., William B. Bankhead National Forest), Madison Co., and Jackson Co. of northern Alabama. We completed searches of museum records (Auburn University Herpetological Collection), Herp-Net records, and prior documented records (Mount 1980) to identify gaps in amphibian and reptile locality data for these counties. Locality records for this account were primarily obtained during a four-year study examining forest management impacts on amphibians and reptiles and through incidental encounters during road cruising and field trips. All GPS coordinates are datum WGS 84. All specimens were verified by Craig Guyer and represent new county records.

CAUDATA — SALAMANDERS

***AMBYSTOMA TIGRINUM* (Eastern Tiger Salamander)**. Lawrence Co.: At the intersection of Alabama State Highway 33 and Alabama State Highway 36 (34.434923°N, 87.292159°W). 1 January 2006. Lamaar Marshall. A single *A. tigrinum* was found climbing a gas pump outside the Black Warrior Trading Post after a rain event. Individual was released after being photographed. AUM AHAP-D 649.

ANURA — FROGS

***ANAXYRUS AMERICANUS* (American Toad)**. Lawrence Co.: Bankhead National Forest, Forest Service road 204 leading to Basin Creek, approximately 100 m from intersection with County Road 2 (34.313048°N, 87.511576°W). 15 May 2010. H. A. Czech, K. Pursel, and D. Sollenberger. Individual was captured on the road and released after being photographed. AUM AHAP-D 651.

***HYLA CINEREA* (Green Treefrog)**. Lawrence Co.: Bankhead National Forest, approximately 1 mile from the Lawrence/Winston county line marker on Alabama State Route 33 South (34.309862°N, 87.33326°W). 3 May 2008. W. B. Sutton. Individual was deceased after being captured in a drift-fence array. AUM AHAP-D 658. Jackson Co.: Boxes Cove, AL Hwy 79 near intersection with Old Larkinsville Road (34.709578°N, 86.107335°W). H. A. Czech. Individual was found on road and released after being photographed. AUM AHAP-D 657.

***HYLA GRATIOSA* (Barking Treefrog)**. Lawrence Co.: Bankhead National Forest, approximately 500 m from Black Warrior Ranger Station on Alabama State Highway 33 South (34.343684°N, 87.342857°W). 25 May 2008. W. B. Sutton and R. Hardman. Individual was found on Alabama State Highway 33 South across from a large open wetland. AUM AHAP-D 659.

***LITHOBATES CLAMITANS* (Green Frog)**. Madison Co.: Beaverdam Creek, approximately 200 m upstream from Monroe Road overpass (34.863390°N, 86.597894°W). 23 September 2010. H. A. Czech, H. Howell, and A. B. Bohlman. AUM AHAP-D 661.

TESTUDINES — TURTLES

***GRAPTEMYS GEOGRAPHICA* (NORTHERN MAP TURTLE)**. Jackson Co.: State Route 146 at the bridge over the Paint Rock River (34.861087°N, 86.196032°W). 1 June 2003. H. A. Czech. Adult female, released after being photographed. AUM AHAP-D 293.

SQUAMATA — LIZARDS

***HEMIDACTYLUS TURCICUS* (Mediterranean House Gecko)**. Covington Co.: Analusia Econolodge, 1421 Martin Luther King Junior Expressway, Andalusia, Alabama 36420 (31.319210°N, 86.456571°W). 6 November 2010. H. A. Czech. AUM AHAP-D 656.

***PLESTIODON INEXPECTATUS* (Southeastern Five-lined Skink)**. Lawrence Co.: Bankhead National Forest, approximately 1 mile from the Lawrence / Winston county line marker on Alabama State Route 33 South (34.309862°N, 87.333263°W). 29 March 2009. Individual was captured underneath an artificial cover object and was released after being photographed. AUM AHAP-D 666.

***PLESTIODON LATICEPS* (Broad-headed Skink)**. Lawrence Co.: Bankhead National Forest, approximately 4 miles down Pine Torch Road from Alabama State Highway 33 South, nearly one-half mile down the yellow horse trail (34.356267°N, 87.299911°W). 19 May 2005. W. B. Sutton. Individual was captured in a drift-fence array and was released after being photographed. AUM AHAP-D 667.

***OPHISAURUS ATTENUATUS LONGICAUDUS* (Eastern Slender Glass Lizard)**. Jackson Co.: The Old Fabius Coal Mine, between the towns of Fabius and Falt Rock (34.80006°N, 85.759213°W). 25 March 2011. T. Barrentine and T. Barrantine. Individual was released after being photographed. AUM AHAP-D 663.

SQUAMATA — SNAKES

***AGKISTRODON P. PISCIVORUS* (Eastern Cottonmouth)**. Jackson Co.: County Road 220 as it crosses through Roseberry Bottoms Swamp, near Scottsboro, AL (34.702476°N, 86.092360°W). 22 March 2012. H. A. Czech. DOR adult male observed and photographed. AUM AHAP-D 647.

***CEMOPHORA COCCINEA COPEI* (Northern Scarletsnake)**. Lawrence Co.: Bankhead National Forest, approximately 1.5 km W of the Black Warrior Ranger Station near Alabama State Route 33 (34.344820°N, 87.354832°W). 23 May 2006. W. B. Sutton. Individual was captured in a drift-fence array and was released after being photographed. AUM AHAP-D 652.

***CROTALUS HORRIDUS* (Timber Rattlesnake)**. Madison Co.: Monte Sano State Park, approximately 1.0 km down firehouse trail from hiking trails parking lot (34.747308°N, 86.503525°W). 15 August 2009. W. B. Sutton and R. H. Hardman. Individual was found dead in the middle of a hiking trail and was photographed. AUM AHAP-D 654.

***PANTHEROPHIS GUTTATUS* (Red Cornsnake)**. Jackson Co.: Near intersection of Alabama Highway 79 and County Road 23 (34.653053°N, 86.109679°W). 23 November 2008. H. A. Czech. Individual was found dead on the road and was photographed. AUM AHAP-D 294.

***PANTHEROPHIS SPILOIDES* (Gray Ratsnake)**. Lawrence Co.: Bankhead National Forest, approximately 1.3 km SSW of the Black Warrior work station, (34.331961°N, 87.339782°W). 13 June 2006. W. B. Sutton. Individual was found crossing a small dirt road within a harvested pine stand. Individual was released after being photographed. AUM AHAP-D 665.

***HETERODON PLATIRHINOS* (Eastern Hog-nosed Snake)**. Winston Co.: Bankhead National Forest, approximately 1.5 km from the intersection of Alabama County road 60 and Kinlock Road north (34.289010°N, 87.493877°W). 30 May 2007. W. B. Sutton. Individual was found on the road near a Loblolly Pine (*Pinus taeda*) plantation and was photographed. AUM AHAP-D 655.

***STORERIA O. OCCIPITOMACULATA* (Northern Red-bellied Snake)**. Lawrence Co.: Bankhead National Forest, approximately 1 km SE of the Black Warrior Work Station (34.335951°N, 87.337106°W). 2 November 2005. W. B. Sutton. Individual was located in a pine-hardwood forest stand in a drift-fence array. Individual was released after being photographed. AUM AHAP-D 670.

***VIRGINIA V. VALERIAE* (Smooth Earthsnake)**. Lawrence Co. Bankhead National Forest, approximately 1 km SE of the Black Warrior Work Station (34.335951°N, 87.337106°W). 10 April 2009. W. B. Sutton. Individual was captured under an artificial cover object in a harvested pine stand. Individual was released after being photographed. AUM AHAP-D 672.

New County Records of Amphibians and Reptiles Resulting from a Bioblitz Competition in Southwestern Georgia, USA

Since the publication of Amphibians and Reptiles of Georgia (Jensen et al. 2008), many new county-level distribution records for amphibians and reptiles have been reported for the state (e.g., Stevenson et al. 2009; Jensen et al. 2011; Stevenson et al. 2011; Butler et al. 2012). Additional contributions to the knowledge of the distribution of amphibians and reptiles have been made through annual bioblitz competitions held primarily between the University of Georgia and Auburn University. A bioblitz competition is an attempt to find and document as many species of defined taxa in a given area, often over a relatively short time period (Graham et al. 2007; Graham et al. 2010a; Graham et al. 2010b; Folt et al. 2013).

From 4–6 October 2013, we organized a bioblitz to search public and private lands in Seminole and Decatur counties, Georgia, USA, which fall in the Upper Coastal Plain. Search efforts focused largely on two large tracts of private land owned by the Reynolds family—Capachequi (Decatur Co.) and Camp Pastures (Seminole Co.). Both tracts include well-managed longleaf uplands, seasonal wetlands, and permanent ponds, and Capachequi borders the Flint River. The bioblitz competition involved more than 30 participants from the University of Georgia, Abraham Baldwin Agricultural College, Clemson University, Western Carolina University, Florida State University, and Sewanee College.

We detected 17 species of amphibians and 33 species of reptiles during of the bioblitz. This included ten new county-level distribution records, which we report here. We vouchered all records with digital photographs. Records were verified by John Jensen and deposited in the Georgia Museum of Natural History. The datum for all GPS locations is WGS 84.

ANURA — FROGS

***ELEUTHERODACTYLUS PLANIROSTRIS* (Greenhouse Frog)**. Seminole Co.: Boat ramp on north shore of Lake Seminole; off of Seminole Sholes Dr. (30.7778°N, 84.8424°W). 5 October 2013. E. Hernandez, S. Horsley, J. Hunt, and E. Jennings. GMNH 50552.

SQUAMATA — LIZARDS

***ANOLIS CAROLINENSIS* (Green Anole)**. Seminole Co.: Near inlet of Lake Seminole; near intersection of Sportsman Rd. and Paradise Dr. (30.8181°N, 84.8797°W). 5 October 2013. E. Hernandez, S. Horsley, J. Hunt, and E. Jennings. GMNH 50554.

***PLESTIODON FASCIATUS* (Common Five-lined Skink)**. Decatur Co.: Capachequi; property of John Reynolds (30.9948°N, 84.5378°W). 5 October 2013. A. Clause, B. Hudson, and K. McEntire. GMNH 50557.

***PLESTIODON INEXPECTATUS* (Southeastern Five-lined Skink)**. Seminole Co.: Camp Pastures; property of John Reynolds (30.8677°N, 84.8047°W; WGS 84). 5 October 2013. D. Filipiak, E. P. Hill, and K. Stohlgren. GMNH 50549.

SQUAMATA — SNAKES

***AGKISTRODON CONTORTRIX* (Copperhead)**. Mitchell Co.: GA 311 near intersection with Sardis Rd. (31.1765°N, 84.4284°W). 6 October 2013. T. Pierson. GMNH 50555. Seminole Co.: River Rd. approximately 300 m S of Fennell Rd. (30.8485°N, 84.9144°W). 5 October 2013. W. Booker, S. Drukker, C. Murphy, B. Romm, and D. Thompson. GMNH 50553.

***AGKISTRODON PISCIVORUS* (Cottonmouth)**. Seminole Co.: Near Dresser Tract of Silver Lake WMA; boat ramp at end of Dresser Landing Rd. (30.8893°N, 84.9343°W). 5 October 2013. J. Barrett, T. Colter, K. Davis, S. Dismuke, W. Moore, K. Pursel, and D. Sollenberger. GMNH 50558.

***NERODIA TAXISPILOTA* (Brown Watersnake)**. Seminole Co.: Boat ramp on north shore of Lake Seminole; off of Seminole Sholes Dr. (30.7778°N, 84.8425°W). 5 October 2013. E. Hernandez, S. Horsley, J. Hunt, and E. Jennings. GMNH 50551.

***OPHEODRYS AESTIVUS* (Rough Greensnake)**. Mitchell Co.: GA 311 approximately 1.2 km SW of intersection with Deer Hole Rd. (31.1150°N, 84.4866°W). 6 October 2013. T. Pierson. GMNH 50556.

***PANTHEROPHIS GUTTATUS* (Red Cornsnake)**. Seminole Co.: Camp Pastures; property of John Reynolds (30.8576°N, 84.8167°W) 5 October 2013. R. Herrington and M. Riddle. GMNH 50550.

Acknowledgments.—All bioblitz activities were carried out under Georgia Department of Natural Resources Scientific Collecting Permits (29-WJH-13-191 and 29-WBH-12-137) and a UGA IACUC AUP (A2012 10-004-YI-A1). We thank the Reynolds family for their hospitality and willingness to let us survey their land and John Jensen of the Georgia Department of Natural Resources for his help in procuring permits and verifying all records. We also thank all participants of the bioblitz for their aid in uncovering new records.

Since the publication of Amphibians and Reptiles of Georgia (Jensen et al. 2008), many new county-level distribution records for amphibians and reptiles have been reported for the state (e.g., Stevenson et al. 2009; Jensen et al. 2011; Stevenson et al. 2011; Butler et al. 2012). Additional contributions to the knowledge of the distribution of amphibians and reptiles have been made through annual bioblitz competitions held primarily between the University of Georgia and Auburn University. A bioblitz competition is an attempt to find and document as many species of defined taxa in a given area, often over a relatively short time period (Graham et al. 2007; Graham et al. 2010a; Graham et al. 2010b; Folt et al. 2013).

From 12–14 April 2013, we organized a bioblitz to search public and private lands in Fannin, Gilmer, and Murray counties, Georgia. Most of this focal area lies near the southwestern terminus of the Blue Ridge ecoregion, with western Murray Co. in the Ridge and Valley, and much of our search effort took place within the Chattahoochee National Forest. The region holds a high diversity of salamanders, and despite being relatively well-studied, a number of herpetofaunal distribution gaps existed—especially for turtles (Jensen et al. 2008). This bioblitz competition involved more than 30 participants from the University of Georgia, Auburn University, the University of Alabama, Virginia Tech, and Pennsylvania State University.

We detected 24 species of amphibians and 20 species of reptiles during the bioblitz. All of the following 14 accounts represent new county records. Ten of these records were collected during the three-county bioblitz, and four were records found outside of the time period and specific geographical bounds of the bioblitz but were obtained within the same general region. We vouchered all records with digital photographs. Records were verified by John Jensen and deposited in the Herpetological Collections of the Auburn University Museum (AUM/AHAP).

CAUDATA — SALAMANDERS

***AMBYSTOMA MACULATUM* (Spotted Salamander)**. Fannin Co.: Old Dial Road, 0.3 road miles N of Tilley Bend Lane (34.80391°N, 84.24628°W; WGS 84). 13 April 2013. T. Pierson, E. White, C. Murphy, W. Lattea, and M. Rajeev. AHAP-D 693. Egg mass. Gilmer Co.: West of Whitepath Road, 1.3 road miles S of Boardtown Road (34.79022°N, 84.42278°W; WGS 84). 12 April 2013. T. Stratmann, C. Carter, K. Fouts, and E. Hernandez. AHAP-D 694.

ANURA — FROGS

***LITHOBATES PALUSTRIS* (Pickerel Frog)**. Murray Co.: Old CCC Camp Road, 4.1 miles W of Mulberry Gap Road (34.81235°N, 84.66039°W; WGS 84). 12 April 2013. B. Folt and J. Jenkins. AHAP-D 698.

***PSEUDACRIS CRUCIFER* (Spring Peeper)**. Fannin Co.: Intersection of Ballewtown Road and Appalachian Highway (34.8478°N, 84.33690556°W; WGS 84). 12 April 2013. H. Vogel, M. Knoerr, D. Drewett, and D. Steen. AHAP-C 0017. Murray Co.: Old CCC Camp Road, 0.8 road miles W of Mulberry Gap Road (34.80223°N, 84.62951°W; WGS 84). 12 April 2013. B. Folt and J. Jenkins. AHAP-D 697.

TESTUDINES — TURTLES

***CHELYDRA SERPENTINA* (Snapping Turtle)**. Towns Co.: Approximately 100 m (airline) WSW of the intersection of Many Forks Road and Many Forks Spur (34.97426°N, 83.93671°W; WGS 84). 12 July 2010. T. Stratmann and B. Hudson. AHAP-D 703.

***CHRYSEMYS PICTA* (Painted Turtle)**. Gilmer Co.: West of Whitepath Road, 1.3 miles S of Boardtown (34.79000°N, 84.42464°W; WGS 84). 12 April 2013. T. Stratmann, C. Carter, K. Fouts, and E. Hernandez. AHAP-D 695. Murray Co.: Highway 225, 0.4 road miles S of Temple Grove Road (34.92406°N, 84.79374°W; WGS 84). 12 April 2013. M. Herr and S. Graham. AHAP-D 701.

***STERNOTHERUS ODORATUS* (Eastern Musk Turtle)**. Gilmer Co.: West of Whitepath Road, 1.3 miles S of Boardtown (34.79022°N, 84.42278°W; WGS 84). 12 April 2013. T. Stratmann, C. Carter, K. Fouts, and E. Hernandez. AHAP-D 696. Union Co.: North of Goose Island Lake, approximately 250 m east of Cozy Acres Lane (34.78914°N, 84.40023°W; WGS 84). 7 June 2010. T. Stratmann and B. Hudson. AHAP-D 705.

SQUAMATA — LIZARDS

***PLESTIODON INEXPECTATUS* (Southeastern Five-lined Skink)**. Gilmer Co.: Alongside East Mountaintown Creek under Chatsworth Highway 52 bridge (34.75033333°N, 84.55582778°W; WGS 84). 13 April 2013. D. Drewett and D. Steen. AHAP-D 674.

***SCINCELLA LATERALIS* (Little Brown Skink)**. Gilmer Co.: South of Woodring Branch Road, 3.5 road miles S of Highway 76 (34.63038°N, 84.64907°W; WGS 84). 13 April 2013. A. Clause, D. Blount, W. Booker, and J. Hunt. AHAP-D 699.

SQUAMATA — SNAKES

***LAMPROPELTIS CALLIGASTER* (Yellow-bellied Kingsnake)**. Towns Co.: Gum Log Road, 0.3 road miles S of Julie Hollow Road (34.96643°N, 83.93502°W; WGS 84). 7 June 2012. T. Stratmann and G. Brown. AHAP-D 704.

***THAMNOPHIS SAURITUS* (Eastern Ribbonsnake)**. Gilmer Co.: Approximately 0.8 miles (airline) NW of the intersection of Lebanon Road and Colwell Church Road (34.92912°N, 94.43818°W; WGS 84). 17 July 2010. T. Stratmann and B. Hudson. AHAP-D 702.

Acknowledgments.—All bioblitz activities were carried out under a Georgia Department of Natural Resources Scientific Collecting Permit (29-WJH-13-191), a USDA Forest Service Research Collection Permit, and a UGA IACUC AUP (A2012 10-004-YI-A1). We thank the landowners for allowing access to private properties and John Jensen of the Georgia Department of Natural Resources for his help in procuring permits and verifying all records. We thank Sean Graham, David Steen, and John Maerz for their roles in organizing, supervising, and participating in the bioblitz. We also thank all participants of the bioblitz for their aid in uncovering new records and Grover Brown and Bryan Hudson for their contribution of additional records.

Recent Distribution Records for *Hyla cinerea* (Green Treefrog) from Tennessee, Southern Kentucky, and Northern Alabama, USA

Most of the following records are vouchered by specimens collected in 2006 as part of a study on the range limits and peripheral range expansion of *Hyla cinerea* in the north-central part of its range. The exceptions are the Benton and Wilson counties, Tennessee records, and two of the Morgan Co., Alabama records. All but two of the voucher specimens and photographs are in the David H. Snyder Museum of Vertebrate Zoology (APSU) at Austin Peay State University, Clarksville, Tennessee. The two exceptions are in the Auburn University Museum (AUM). Vouchers in the APSU collection were verified by A. Floyd Scott; Craig Guyer verified the identification of the Auburn University Museum specimens. County record status was determined using Mount (1975) and Redmond and Scott (1996, with updates online). Datum for geographic coordinates is WGS 84.

ALABAMA

Colbert Co.: North shore of Colbert Bay, bay of Pickwick Lake (impounded Tennessee River) (34.8394°N, 87.9472°W). Adult perched on branch of small tree. 22 September 2006. Nathan Parker and Larry Derrick. APSU 18793 (color photo). First county record.

Lauderdale Co.: Near Lauderdale CR-2 bridge across Colbert Creek (34.8517°N, 87.9261°W). Adult perched on Cattail (*Typha latifolia*) and juvenile found dead on road (DOR). 22 September 2006. Nathan Parker and Larry Derrick. APSU 18794-95 (color photos). First county record.

Lawrence Co.: Just south of inundated Mallard Creek, bay of Pickwick Lake (impounded Tennessee River) (34.6861°N, 87.1631°W). Juvenile alive on road (AOR). 24 September 2006. Nathan Parker. APSU 18800 (color photo). First ounty record.

Limestone Co.: Road through marshy area along unnamed tributary to Limestone Slough (34.6303°N, 86.8583°W). AOR juvenile. 23 September 2006. Nathan Parker. APSU 18796 (color photo). First county record.

Madison County: Road through marshy area, inundated lower Barren Fork Creek, bay of Wheeler Lake (impounded Tennessee River) (34.6153°N, 86.7344°W). AOR juvenile. 23 September 2006. Nathan Parker. APSU 18797 (color photo). First county record.

Morgan Co.: Beaver swamp at Cold Spring near edge of Tennessee River floodplain (34.5469°N, 86.8506°W). Two juveniles climbing on tree trunk and woody vine. 23 September 2006. Nathan Parker. APSU 18798–99 (color photos). Wheeler National Wildlife Refuge, south side of Tennessee River (34.5433°N, 86.8471°W). Specimen on shrub. 21 April 2003. W. R. Gates and T. Petty. AUM 36423. First county records.

KENTUCKY

Trigg Co.: Shoreline of inundated lower Little River, bay of Lake Barkley (impounded Cumberland River) (36.8317°N, 87.9311°W). Adult male calling from blackberry cane (*Rubus* sp.). 12 July 2006. Nathan Parker. APSU 18203 (color photo). First Little River drainage record.

TENNESSEE

Benton Co.: Mouth of Harmon Creek, bay of Kentucky Lake (impounded Tennessee River) (36.1472°N, 87.9514°W). Three adult males taken at night from willow (*Salix* sp.) bushes in ca. 1 m deep water, ca. 30 m from bank. 28 June 2001. Scott Williamson. APSU 3277 (alcohol specimen). First county record.

Cheatham Co.: Cheatham Lake Wildlife Management Area, Cumberland River floodplain, Marks Creek Slough adjacent to Cumberland Bicentennial Trail (36.2914°N, 87.0953°W). Adult male calling from Buttonbush (*Cephalanthus occidentalis*). 23 June 2006. Nathan Parker. APSU 18183 (color photo). First county record.

Davidson Co.: 1) Scottsboro area, floodplain of Cumberland River near river mile 168.5, east bank (36.1875°N, 86.9378°W). Adult male calling from Black Willow (*Salix nigra*) sapling. 23 June 2006. Nathan Parker. APSU 18184 (color photo). 2) Nashville, west side of Cumberland River just north of the Briley Parkway (TN Hwy. 155) Bridge (36.1833°N, 86.8669°W). 18 August 2006. Vic Scoggin. APSU 18212–13 (color photos). 3) Shelby Bottoms Nature Center (36.1933°N, 86.7037°W). Adult observed sitting on leaf of *Vitus* sp. 28 August 2012. Denise Weyer. APSU 19374. First Davidson Co. records; first records from Outer Nashville Basin (EPA Ecoregion 71h- Griffith et al. 1998).

Dickson Co.: Floodplain of Harpeth River near confluence of Harpeth and Cumberland rivers, on Dozier Boat Dock Road (36.2986°N, 87.1514°W). AOR adult. 28 August 2006. Nathan Parker. APSU 18792 (color photo). First county record and first Harpeth River drainage record.

Hardin Co.: Mouth of Bruton Branch, bay of Pickwick Lake (impounded Tennessee River) (35.0697N, 88.1836W). Two adult males, one calling from base of Buttonbush, the other from Halberd-leaved Rose Mallow (*Hibiscus laevis*). 5 August 2006. Nathan Parker. APSU 18191, 18192 (color photos). Augments the only other published record for the county (Summers 2010).

Humphreys Co.: Two new records that augment the only published record for the county (Scott et al. 2000): 1) Mouth of Bear Creek, bay of Kentucky Lake (impounded Tennessee River) (36.1131°N, 87.9136°W). Two adult males calling from Black Willow and Buttonbush. 4 July 2006. Nathan Parker. APSU 18207–08 (alcohol specimens). 2) Floodplain of Duck River near SR-13 bridge (35.9369°N, 87.7628°W). Adult male calling from beneath thatch at edge of inundated grassy area. 5 July 2006. Nathan Parker. APSU 18200 (alcohol specimen). Furthest upstream record in Duck River drainage.

Montgomery Co.: Several new records that augment the only published record for the county (Sutton et al. 2004): 1) Dotsonville community, Buckner Pond (36.4817°N, 87.4853°W). Adult male calling from leaf of swamp iris (*Iris* sp.). 3 June 2006. Nathan Parker. APSU 18787 (color photo). 2) Shelton Ferry Wildlife Management Area (SFWMA), beaver marsh on Dawson Creek near edge of Cumberland River floodplain (36.4139°N, 87.2939°W). Adult male calling from Buttonbush. 19 June 2006. Nathan Parker. APSU 18788 (color photo). First record from SFWMA, which was the subject of a herpetofaunal survey in 1994 (Rozelle and Scott 1995). 3) Clarksville, Cumberland River floodplain near Clarksville Fairgrounds (36.5119N, 87.3672W). Amplectant pair and lone adult male, both on stems of Silver Maple (*Acer saccharinum*). 28 June 2006. Nathan Parker. APSU 18789-90 (color photos). 4) Haynes Bottom Wildlife Management Area (HBWMA), north shore of slough in floodplain of Cumberland River (36.4514°N, 87.4917°W). Adult male calling from introduced bush honeysuckle (*Lonicera* sp.). 14 August 2006. Nathan Parker. APSU 18791 (color photo). First record from HBWMA, which was the subject of a herpetofaunal survey in 1998–1999 (Scott and Williamson 1999).

Perry Co.: Southern Lobelville/ Beardstown area, along SR-13 just above edge of Buffalo River floodplain (35.6978°N, 87.8017°W). Adult male calling from herbaceous vegetation at margin of small cattle pond. 10 July 2006. Nathan Parker. APSU 18201 (alcohol specimen). First Perry Co. record; southernmost Buffalo River drainage record.

Rutherford Co.: Poole Knobs Recreation Area, peninsula in Percy Priest Lake (impounded Stones River) (36.0400°N, 86.5067°W). DOR, gravid female. 11 August 2006. Nathan Parker. APSU 18204 (alcohol specimen). First county record, first Stones River drainage record, easternmost record in Cumberland River drainage, and first record from Inner Nashville Basin, (EPA Ecoregion 71i- Griffith et al. 1998).

Tipton Co.: Centennial Island (35.3908°N, 90.1589°W). Two individuals, one adult male and one juvenile, in grassy puddle in cotton field. 8 July 2006. Nathan Parker. APSU 18202, 18206 (alcohol specimens). First county records. Augments the only published record for the county (Summers 2010).

Wilson Co.: Mt. Juliet, Clovercroft Trail (36.2622°N, 86.5611°W). 23 June 2012. Dennis Crumby. APSU 19255 (color photo). First county record.

Acknowledgments.—I thank Larry and Deborah Derrick, Hala Parker, Miranda Herrick, and Thomas Payne for field assistance, Dennis Crumby for the Jackson Co., TN record, Vic Scroggin for one of the Davidson Co., TN records, Craig Guyer for two of the Morgan Co., AL records, Floyd Scott for guidance and reviewing the manuscript, Austin Peay State University's Center of Excellence for Field Biology for providing funding and use of equipment, and the numerous public and private landowners who permitted me to search for frogs on their properties.

NATURAL HISTORY NOTES

CAUDATA — SALAMANDERS

***DESMOGNATHUS QUADRAMACULATUS* (Black-bellied Salamander). DIET.** *Desmognathus quadramaculatus* (Plethodontidae) is found in mountainous regions from southern West Virginia south to northern Georgia (Petranka 1998. Salamanders of the United States and Canada, pp. 282–287. Smithsonian Institution Press, Washington, DC, 587 pp.). Herein I report on the inclusion of yellow jacket wasps (*Vespula* sp.) in the diet of a wild *D. quadramaculatus*.

At ~0840 h, on 25 October 2012, I observed a young adult *D. quadramaculatus* after turning a stone in a small first-order stream in Rich Mountain Wildlife Management Area, Gilmer Co., Georgia, USA (34.77847°N, 84.30125°W, datum WGS84; elev. 681 m). Upon capture, the specimen regurgitated its stomach contents, which included the partial remains of at least two yellow jacket wasps (*Vespula* sp.; Fig. 1). Hymenopterans and "aerial prey" have been documented in dietary studies of *D. quadramaculatus* (Martof and Scott 1957. Ecology 38:494–501; Davic 1991. J. Herpetol. 25:108–111). However, no predation on *Vespula* has been previously reported and to my knowledge this is the first documentation of this genus in the diet of *D. quadramaculatus*. Of further interest is that the salamander showed no obvious symptoms or injuries related to anti-predatory wasp stings.

PHOTO BY ROBERT L. HILL

FIG. 1. *Desmognathus quadramaculatus* with regurgitated remains of *Vespula sp.*

Editorial assistance provided by J. R. Mendelson, III, and wasp identification confirmed by M. Goodisman.

***NECTURUS MACULOSUS* (Mudpuppy). DIET.** Our surveys for *Necturus maculosus* (see below; Cochran and Borash 2014. Herpetol. Rev. 45:301–302) provided data on diet in a region where little information is available. Mudpuppies were collected by backpack electrofishing (pulsed DC) at three locations in tributaries of the Mississippi River in Minnesota, USA: Salem Creek, Dodge Co., 14 May 2009 (N = 5; mean total length = 24.5 cm); Upper Iowa River downstream, Fillmore Co., 07 April 2009 (N = 1; total length = 29 cm); Upper Iowa River upstream, Fillmore Co., 02 June 2009 (N = 1; total length = 17.4 cm). For precise locations of these sites, see Cochran and Borash 2014 (*op. cit.*) Gut contents were obtained by gastric lavage with a plastic squirt bottle, and, in one case, from a fecal pellet released by a specimen held overnight.

Based on previous reports (e.g., Harris 1959. Field and Laboratory 27:105–111; Cochran and Lyons 1985. Herpetol. Rev. 16:53), it was not surprising that six of seven mudpuppies had eaten aquatic insects (Table 1). However, all five Mudpuppies from Salem Creek had eaten Green Frog (*Lithobates clamitans*) tadpoles, and one contained an earthworm and a slug on a day when a recent rain had washed many of both taxa into the stream. One 25-cm Mudpuppy from Salem Creek contained a 46-mm Rainbow Darter (*Etheostoma caeruleum*), and another contained small ctenoid fish scales that were most likely from a darter. The freshness of the darter raised the possibility that it

TABLE 1. Prey items recovered from Mudpuppies (*Necturus maculosus*). The total number of prey of each type is indicated, along with the fraction of stomachs in which each prey type occurred and the lengths of individual prey items that were relatively intact. * = from walking legs.

Prey type	Number	Frequency	Prey length (mm)
Earthworm	1	1/7	84
Slug	1	1/7	13
Crayfish	2 claws*	1/7	
Heptageneid mayfly nymphs	13+	4/7	5,9,10
Caddisfly larval cases	2	2/7	
Tipulid cranefly larva	1	1/7	36
Chironomid midge larvae	4	2/7	5,6
Arthropod fragments	N/A	1/7	
Rainbow Darter	1	1/7	46
Ctenoid fish scales (darter?)	6	2/7	
Green Frog tadpoles	7	5/7	25,45

had been eaten in the collecting bucket; however, Mudpuppies are known to feed at least occasionally on fish (Thomas et al. 2007. Herpetol. Rev. 38:433–434, and references therein).

We thank Melissa Markert, Cassandra Hulett, and Rebecca Snyder for assistance in the field. Liz Harper of the Minnesota Department of Natural Resources facilitated our Mudpuppy survey, which was funded by a contract from that organization.

PHILIP A. COCHRAN (e-mail: pcochran@smumn.edu) and **GARY M. BORASH**, Biology Department, Saint Mary's University of Minnesota, 700 Terrace Heights, Winona, Minnesota 55987, USA.

***NECTURUS MACULOSUS* (Mudpuppy). HABITAT.** Our surveys of streams in southeastern Minnesota, USA in 2009 provided data on distribution and habitat of *Necturus maculosus* in a region where little information is available. Mudpuppies were collected by backpack electrofishing (pulsed DC) in several drainages tributary to the Mississippi River (Table 1). Habitat data for most stream reaches where Mudpuppies were captured were obtained at equally-spaced intervals along a series of 10 randomly selected transects across the stream. Current velocity in the water column (0.6 × depth) and at the bottom was measured when possible with an Owen River Hydroprop. Substrate within a 30-cm radius of each point was categorized by visual estimation of percentage composition of bedrock, boulder (> 30 cm), large cobble (15–30 cm), small cobble (2.5–15 cm), gravel (0.2–2.5 cm), sand (< 0.2 cm), silt (suspendable sediment), and "other" (usually organic debris). Single measurements of temperature, dissolved oxygen, and specific conductance were obtained at most stream reaches.

Stream reaches with Mudpuppies were relatively large in comparison to streams without Mudpuppies. They tended to be relatively wide and to be dominated by coarse, hard substrate (Table 1). They usually were dominated by riffles and runs and were well oxygenated. Within each stream reach where Mudpuppies occurred, the actual sites of collection tended to be within runs in areas where slab rock was present, often exposed as shelving outcrops along the bank margins. Electrofishing was not efficient at pulling Mudpuppies from beneath the cover of large rock slabs; we sampled the North Branch Root River site five times before collecting a Mudpuppy.

During surveys in 2009, we sampled 25 sites on 17 streams, and during similar sampling in 2008, we sampled 53 sites on 30 streams. We did not find Mudpuppies in any of the 22 coldwater trout streams we sampled. Fish species collected at each of the sites with Mudpuppies are typical of cool- or warm-water streams: Common Shiner (*Notropis cornutus*), stoneroller

TABLE 1. Habitat data for stream reaches where Mudpuppies (*Necturus maculosus*) were collected in 2009. Number of measurements is indicated in parentheses after each mean, and for some measurements ranges are also provided. At the North Branch Root River, a single transect was established at the site of Mudpuppy capture.

(*Campostoma* spp.), Hornyhead Chub (*Nocomis biguttatus*), Bluntnose Minnow (*Pimephales notatus*), White Sucker (*Catostomus commersoni*), Rock Bass (*Ambloplites rupestris*), and Johnny (*Etheostoma nigrum*), Rainbow (*E. caeruleum*), and Fantail Darters (*E. flabellare*). Stonecats (*Noturus flavus*) were found with Mudpuppies at all but one of the Upper Iowa River sites; like the Mudpuppy, this species is strongly associated with rock slabs or boulders.

We thank Melissa Markert, Cassandra Hulett, and Rebecca Snyder for assistance in the field. Liz Harper of the Minnesota Department of Natural Resources facilitated our Mudpuppy survey, which was funded by a contract from that organization.

PLETHODON CHATTAHOOCHEE **(Chattahoochee Slimy Salamander). PREDATION.** Relatively few instances of predation upon members of the *Plethodon glutinosus* complex have been reported. To our knowledge, predation by *Thamnophis sirtalis* (Common Gartersnake) has been reported for *P. cylindraceus* (Uhler et al. 1939. Trans. Am. Wildl. Conf. 4:605–622), *P. albagula* (Konvalinka and Trauth 2003. Herpetol. Rev. 34:378), and *P. glutinosus* (McCoard 2008. Unpubl. MS Thesis. Marshall University). Here, we report the first documented instance of predation of *P. chattahoochee* by *T. sirtalis*. At approximately 1400 h on 13 April 2013, we encountered a small adult *T. sirtalis* swallowing the last few inches of the tail of an adult *P. chattahoochee* in Fannin Co., Georgia, USA (34.73923°N, 84.141092°W, datum: WGS 84). Upon being discovered, the snake rapidly swallowed the remainder of the salamander and crawled away (Fig. 1). Soil and leaf litter were stuck to the face and snout of the snake presumably due to the defensive skin secretions produced by the salamander.

SIREN LACERTINA **(Greater Siren). HABITAT.** Typically, *Siren lacertina* is associated with permanent or semi-permanent freshwater marshes, rivers, lakes and other freshwater bodies throughout the southeastern United States (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Books, Washington, DC. 587 pp.). Though some salamanders have displayed salt tolerance, including *Siren lacertina* (Neill 1958. Bull. Mar. Sci. Gulf Caribb. 8:1–96) and the closely related *S. intermedia* (Asquith and Altig 1986. Comp. Biochem. Physiol. 84:683–685), observations of estuarine water habitat usage by caudates is rare in the literature.

On 04 May 2013, while conducting aquatic surveys using standard aquatic funnel traps in Everglades National Park, Dade Co., Florida, USA, two *S. lacertina* were trapped at a sampling site directly adjacent the Main Park Rd near the Hell's Bay canoe trail launch (25.232367°N, 80.823283°W; datum WGS 84). The habitat was a monoculture of Red Mangrove (*Rhizophora mangle*), and salinity was measured with a refractometer (Cole-Parmer RHS-10/ATC). Salinity at the time of capture was 4 ‰, indicative of the oligohaline mixing of upper estuaries typical in the southern Everglades (Davis et al. 2005. Wetlands 25:832–842). Specimens were photographed, but not vouchered due to permit constraints. This represents the first documented instance of mangrove swamp habitat usage and one of only two (Neill, *op. cit.*) known instances of tolerance of saline conditions by *S. lacertina*. Red mangrove provides a highly structured habitat that *S. lacertina* may prefer given its well-known preference for such microhabitats (Petranka, *op. cit.*).

This work was conducted under Everglades National Park Permit #EVER0013 and partially funded by a Palm Beach Atlantic University Quality Initiative Grant.

TRITURUS IVANBURESCHI **(Buresch's Crested Newt). DEFENSIVE BEHAVIOR.** Defensive behaviors of salamanders have been well reviewed (Brodie et al. 1974. Herpetologica 30:79–85; Brodie 1977. Copeia 1977:523–535). *Triturus ivanbureschi* is a member of the *T. karelinii* group (Salamandridae), which is distributed over the south-eastern Balkan Peninsula, covering most of Bulgaria, eastern parts of Greece, eastern Republic of Macedonia, Serbia, European and Asian Turkey (western parts up to ca. 300 km inland; Wielstra et al. 2013. Zootaxa 3682:441–453). To date, the defensive behavior of this species has not been described.

On 5 April 2005, one of us (PB) found and photographed a subadult specimen of *T. ivanbureschi* near Primorsko in southeastern Bulgaria (42.31435°N, 27.75773°E, datum WGS 84; elev. 103 m). The specimen was found under a stone together with a specimen of the snake *Malpolon insignitus*. The salamander coiled its tail and upper part of the body while was being handled. After releasing it on the ground, the salamander remained in the same position, then it also crooked its front and back finger tips, closed its eyes, lifted up the back part of its body above ground at which time we observed the aposematic coloration on the ventral part of its body (Fig. 1A, B). It remained in this position for two minutes and after that it returned to its normal position.

We observed three of the basic antipredator behaviors typical of salamandrids: defensive posture, immobility, and presentation of ventral aposematic coloration (Brodie et al. 1974, *op. cit.*; Brodie 1977, *op. cit.*; Grillitsch 1983. Salamandra 20:61–63; Marco and Leguía 2001. Rev. Esp. Herpetol. 15:5–11). By exposing brightly colored parts of the body, individuals warn (or possibly confuse,

FIG. 1. *Triturus ivanbureschi* in defensive posture. A) lateral view. B) dorsal view.

see Batesian mimicry) their potential predators about noxious or toxic skin secretions, which is well known in many species of amphibians (cf. Brodie et al. 1974, *op. cit.*; Brodie 1977, *op. cit.*; Toledo et al. 2011, *op. cit.*). In addition, by coiling in an immobile position, the salamander probably hampers recognition as prey by a snake, bird, or mammal predator.

DANIEL JABLONSKI, Department of Zoology, Comenius University in Bratislava, Mlynská dolina B-1, 842 15, Bratislava, Slovakia (e-mail: daniel.jablonski@balcanica.cz); **PETR BALEJ**, Zdeňka Bára 114/4, 700 30 Ostrava, Czech Republic.

ANURA — FROGS

***ANAXYRUS BOREAS* (Western Toad). PREDATION.** Unpalatability to predators is a well-documented defense mechanism found in several families of amphibians (Peterson and Blaustein 1990. Ethol. Ecol. Evol. 3:63–72). However, there is some debate over whether larval amphibians benefit from chemical defenses. A review of the palatability of amphibian larvae revealed they were consumed by predators in 89% of experimental trials. Furthermore, even though bufonid larvae are often considered unpalatable, they were consumed at similar rates as all other species (Gunzburger and Travis 2005. J. Herpetol. 39:547–571). Nonetheless, bufonid eggs and hatchlings may be less palatable than older larval stages (Brodie and Formanowicz 1987. Herpetologica 43:369–373).

Anaxyrus boreas is an example of a species that uses chemical defenses against predators (Peterson and Blaustein 1990, *op. cit.*). On 23 May 2013, we observed a congregation of nine adult Barred Tiger Salamanders (*Ambystoma mavortium*) consuming recently-hatched boreal toad larvae (Gosner stage 20–23) at a constructed wetland near Moran, Wyoming, USA (43.832443°N, 110.35512°W, datum: WGS 84). After capturing three salamanders (all males) for a mark-recapture study we observed that their stomachs were noticeably engorged. The salamanders were anesthetized with MS-222 prior to PIT-tagging. As the salamanders were recuperating, but still unconscious, we observed tadpoles swimming out of their mouths. We monitored the salamanders for another hour after they awakened but no other tadpoles emerged. All tadpoles appeared un-masticated with no visible injury.

Previous accounts have suggested larval tiger salamanders might prey upon *A. boreas* tadpoles (Dodd 2013. Frogs of the United States and Canada, Volume 1. The Johns Hopkins University Press, Baltimore, Maryland. 460 pp.), which our observations now verify. Perhaps because the salamanders are suction feeders that engulf, rather than chew their prey, they were less affected by toxins that may have been present in the hatchlings (Pearl and Hayes 2002. Am. Midl. Nat. 147:145–152).

We thank A. Sepulveda for comments that improved the manuscript. This manuscript is Amphibian Research and Monitoring Initiative (ARMI) product no. 467.

***BUFO BUFO* (Common Toad). PREDATION.** On 22 March 2012, during an amphibian survey in Cuenca province, in eastern Spain (40.02250°N, 1.98288°W, datum: WGS84), an Ardea cinerea (Grey Heron) was found trying to swallow a large, female Bufo bufo. The heron flew to the top of a nearby tree. The heron had pierced the body cavity of the toad with its beak, revealing egg strings dangling from the injury. After a few minutes the heron came back to the pond, and continued trying to clean the toad in the water. Handling of the prey continued for more than ten minutes, and later the heron fled away from the pond with the toad in its beak. Throughout the predation event the toad appeared motionless and we assumed it was dead. We are uncertain whether the heron eventually consumed the toad. Taking into account that the observation was coincident with the breeding season of A. cinerea in Spain, it is possible that the toad could be transported to the nest to feed the fledglings.

Ardea cinerea is opportunistic predator; its diet consists mainly of fish, but it can prey on amphibians, reptiles, birds, and even mammals (Kushlan and Hancock 2005. The Herons. Oxford University Press, Oxford, U.K. 433 pp.). Usually its prey is swallowed without handling. But during this observation we witnessed a long period of handling of the prey by the heron. This was probably due to the presence of parotid glands, and also due to the presence of eggs protruding from the female toad, which are also unpalatable and toxic (Litch 1968. Herpetologica 24:93–98). *B. bufo* is usually discarded by predators due to its toxicity.

Some predators are able to cope with this problem using specific handling techniques, e.g., "progressive skinning" (Slater 2002. IUCN Otter Spec. Group Bull. 19:25–29), as in Eurasian otters (*Lutra lutra*; Ayres and García 2011. Mammal. Biol. 76:90–92). *A. cinerea* harpoons its prey, and the only handling technique that is used is washing the prey before swallowing it.

ENRIQUE AYLLON (e-mail: enrique.ayllon@herpetologica.org) and **CESAR AYRES** (e-mail: cesar@herpetologica.org), Asociación Herpetológica Española, Apdo. 191, 28911, Leganes, Madrid, Spain.

***HYLOSCIRTUS PALMERI* (Palmer's Treefrog). PREDATION.** Anurans are often the most abundant terrestrial vertebrates in tropical regions, and they are widely available as prey for other vertebrates (Vitt and Caldwell 2009. Herpetology: An Introductory Biology of Amphibians and Reptiles. Third Edition. Academic Press, San Diego. 697 pp.) and invertebrates (Toledo 2005. Herpetol. Rev. 36:395–400). Among invertebrates, spiders are potential predators of anurans (Toledo et al. 2007. J. Zool. 271:170–177). Few reports have documented arboreal anurans as prey of spiders (e.g., Ortega-Andrade et al. 2011. Pap. Avulsos Zool. 51:1–19; Almeida-Reinoso and Coloma 2012. Herpetol. Rev. 43:126).

At 2120 h on 19 January 2009, during a field survey in El Palmar Creek, La Sonrisa village, municipality of Samaná, Department of Caldas, Colombia (5.61500°N, 74.95720°W, datum: WGS84, elev. = 714 m), an individual of *Xenesthis immanis* (Araneae: Theraphosidae) was observed carrying an individual of *Hyloscirtus palmeri* (Hylidae) in its chelicerae and moving between rocks along the creek. We did not collect the spider and frog, because the spider escaped with its prey and jumped into the water when we tried to capture them. Both species are widely distributed and well-represented in the region, and we have over five years' experience researching the ecology of frogs and spiders in the area. The spider is a large species with a conspicuous coloration (metallic purple) facilitating its recognition in the field. LER-O confirmed the identity of the spider.

Globally, wandering spiders (Ctenidae) and fisher spiders (Pisauridae) have been recorded as the most common predators of anurans (Da Costa et al. 2006. Herpetol. Rev. 37:337–338; Melo-Sampaio et al. 2012. Herpetol. Rev. 43:636–637), whereas predation by tarantulas on anurans is not frequently documented (e.g., Ortega-Andrade et al. 2011, *op. cit.*). To our knowledge, this is the first report of predation on the frog *H. palmeri* by the tarantula *X. immanis*.

***LEPTODACTYLUS MACROSTERNUM* (Rã-Caçote). DIET.** *Leptodactylus macrosternum* is a medium-sized nocturnal anuran with a diet consisting mainly of arthropods. Species of this genus are considered generalists and can adapt to disturbed areas. Studies on the natural history of leptodactylidae indicate that crustaceans are present in their diet (De-Carvalho et al. 2008. Biota Neotrop. 18:105–115). These include amphipods and isopods, and less frequently, decapod crustaceans. To investigate the diet of *L. macrosternum*, we collected 30 specimens of *L. macrosternum* on 12 September 2011 in one weir (located in the municipality Milagres, Ceará State, northeastern Brazil (7.301872°S, 38.98416°W; WGS 84). The analysis of the stomach contents of the frogs showed the presence of the shrimp *Macrobrachium jelskii* (Crustacea: Decapoda), in one of the specimens of *L. macrosternum* collected. This constitutes the first decapod known in the diet of this species.

***LITHOBATES CATESBEIANUS* (American Bullfrog). HABITAT.** *Lithobates catesbeianus* is common throughout its native range in eastern North America. They are highly aquatic frogs and are usually associated with permanent bodies of water where breeding occurs (Casper and Hendricks 2005. *In* Lannoo et al. [eds.], Amphibian Declines: The Conservation Status of United States Species, pp. 540–556. Univ. California Press, Berkeley). However, *L. catesbeianus* is occasionally encountered in terrestrial, upland habitats (Bohnsack 1952. Copeia 1952[2]:114; Bennett et al. 1980. Am. Midl. Nat. 103:412–416; McLeod and Gates 1998. Am. Midl. Nat. 139:164–177), which is likely often the result of juvenile dispersal (Casper and Hendricks, *op. cit.*). These few reports of the use of the terrestrial environment by *L. catesbeianus* indicate that this may be an underappreciated aspect of its ecology that requires further documentation. Here, I report juvenile *L. catesbeianus* occupying refugia in a dried temporary pool. On 22 October 2013, I visited the dry basin of an ephemeral pond located in a forest in State Game Lands #176, Centre Co., Pennsylvania, USA (40.795478°N, 77.952322°W; datum WGS 1984). This small pond (<0.1 ha) is typically dry throughout the summer and autumn but supports the larvae of the vernal pool specialists *L. sylvaticus* (Wood Frog), *Ambystoma maculatum* (Spotted Salamander), and *A. opacum* (Marbled Salamanders). I overturned approx. 20 stones (ranging from approx. 15–45 cm in length), which were partly sunk into the soil, while searching for *A. opacum* nests. Under 4 stones, I instead found individual juvenile *L. catesbeianus* (approx. 4 cm SVL). They were crouching in depressions under the stones and were relatively inactive despite the disturbance. There was no standing water or any excess moisture under these or any stones in the pond basin. The short hydroperiod of this pond makes it almost certain that these frogs underwent their larval period in another, more permanent pond; the nearest such pond known to support *L. catesbeianus* is approx. 750 m away. Given the apparent age of the frogs, I assume they probably metamorphosed several months prior in the summer and were dispersing through upland habitats to locate new breeding ponds (Willis et al. 1956. Copeia 1956:30–41) and may have been hibernating in this location during their post-metamorphic dispersal. *L. catesbeianus* are likely capable of

successfully overwintering in dried ephemeral ponds. Although aquatic hibernation is typical, one report of terrestrial hibernation of *L. catesbeianus* supports this possibility (Bohnsack, *op. cit.*), and the number of individuals I observed within the pond basin suggests that they may select terrestrial refuges in locations likely to be inundated with water.

BRADLEY E. CARLSON, Biology Department and IGDP in Ecology, The Pennsylvania State University, University Park, Pennsylvania 16802, USA; e-mail: bec169@psu.edu.

***LITHOBATES CLAMITANS MELANOTA* (Northern Green Frog). MYIASIS.** At 1300 h on 22 July 2013, southwest of the Powdermill Nature Reserve, Westmoreland Co., Pennsylvania, USA (40.155243°N, 79.288798°W, datum WGS84; elev. 461 m), I observed and photographed an adult female *Lithobates clamitans melanota* exhibiting widespread symptoms of ectoparasitism by dipteran eggs (2–4 mm). The frog was 86 mm SVL and 45 mm in tibia–fibula length. Cursory examination of the specimen from a distance showed it to be alive, ambulatory, but with obvious signs of tissue damage, impaired motor skills, and other physical stresses (Fig. 1). When approached, the frog would make quick spasmodic movements displacing several adult dipterans. Intermittent and sequential stops by the frog would result in the return of the mature flies. After capture and closer examination, the cloaca, axillary creases, groin folds, and various mid-body lacerations exhibited an extensive degree of infestation. This pathological condition is technically known as myiasis. The frog exhibited an extensive degree of wound and cutaneous myiasis (Fig. 1). For this individual, the high levels of soft tissue damage and the clear signs of morbidity appeared to be reaching fatal stages. The dipteran species responsible for this condition was not identified.

Several cases of amphibian myiasis have been described in North America. For instance, in Colorado, *Anaxyrus boreas* (Boreal Toad) was parasitized by the blowfly larvae of *Bufolucilia elongata* (James and Maslin 1947. J. Washington Acad. Sci. 37:366–368). In California, *L. catesbeianus* (American Bullfrog) was observed exhibiting ophthalmic myiasis by the larvae of *B. silvarum* (Anderson and Bennett 1963. Can. J. Zool. 41:1169–1170). In Wisconsin, several individuals from a population of juvenile *L. sylvaticus* (Wood Frog) were observed exhibiting fatal myiasis induced by larvae of *B. silvarum* and *B. elongata* (Bolek and Janovy 2004. J. Parasitol. 90:1169–1171). To my knowledge the observation reported herein represents the first record of fatal myiasis in *L. c. melanota*.

I thank the staff of the Powdermill Nature Reserve (PNR) and the Carnegie Museum of Natural History, especially the Director of PNR, John W. Wenzel.

DANIEL F. HUGHES, Powdermill Nature Reserve, 1847 Route 381, Rector, Pennsylvania, 15677, USA; e-mail: dfhughes@miners.utep.edu.

***LITHOBATES HECKSCHERI* (River Frog). MASS METAMORPHOSIS.** River Frog tadpoles are well known for their unique (among eastern North American ranids) schooling behavior (Altig and Christensen 1981. J. Herpetol. 15:151–154), which likely contributes to relatively equal growth of siblings because each tadpole within a school is exposed to similar water temperatures and foraging conditions. Consequently, near-synchronous metamorphosis of entire cohorts in this species should not be unexpected. Several observations of mass emergences have indeed been made (Wright and Wright 1933. Handbook of Frogs and Toads. Comstock Publishing Associates, Ithaca, New York. 652 pp.; Herrington 2009. Georgia J. Sci. 67:38) but only rough guesses (e.g., "thousands") as to the number of froglets involved were attempted.

On 31 May 2013 in Lee Co., Georgia, USA, in a swamp associated with a tributary of Muckalee Creek (31.816036°N, 84.132703°W; WGS 84), one of us (JW) encountered a tremendously large aggregation of transforming frogs along and adjacent to the bank of the wetland. Photographs were taken and sent to JBJ for positive identification as River Frogs. JW estimated that frogs seen depicted here (Fig. 1) represented about one-fifth of the entire aggregation. At least 856 individual river frogs were counted in the Fig. 1 photograph, which makes the full aggregation likely in excess of 4000 individuals. The same large aggregation was observed again on 06 June 2013, but when next visited on 15 June 2013 it had completely disappeared because the froglets likely dispersed (or were eaten). The clutch size of a single female River Frog ranges from 5000–14,000 eggs (Dodd 2013. Frogs of the United States and Canada. Johns Hopkins University Press, Baltimore, Maryland. 1032 pp.), so it is quite possible that many, or perhaps all, of the frogs observed were siblings. Schooling

FIG. 1. Lateral view of an adult female Northern Green Frog, *Lithobates clamitans melanota*, exhibiting widespread symptoms of myiasis.

FIG. 1. Recently transformed River Frogs, *Lithobates heckscheri*, in a Lee Co., Georgia, USA swamp.

behavior facilitated by kin recognition has been documented in American Toads (*Anaxyrus americanus*) and other species (Dodd 2013, *op. cit.*), but this not been studied in River Frogs.

Despite the abundance and availability of prey, neither Herrington (2009, *op. cit.*) nor we saw any anuran predators (such as wading birds) among our observed emergence aggregations, suggesting that perhaps metamorphosing River Frogs are noxious or distasteful, as has been suggested though unproven of their tadpoles (Altig and Christensen 1981, *op. cit.*). Alternatively, such mass emergences could be adaptive and result in predator satiation, as with periodic cicadas (Williams et al. 1993. Ecology 74:1143–1152). Further research is clearly needed to explain the mechanisms involved in, and the survival strategies of, such synchronous emergences of metamorphosing River Frogs.

We thank Dirk Stevenson for helpful suggestions on this note.

***LITHOBATES PALMIPES* (Green Rana). FORELIMB MALFORMATION.** The considerable increase in the number of records of malformations in amphibians has drawn the attention of many researchers (Meteyer et al. 2000. Teratology 62:151–171). On 22 May 2011, 16 *Lithobates palmipes* tadpoles were collected from a pond located in the São Nicolau Farm in the municipality of Cotriguaçu, Mato Grosso, Brazil (9.819417°S, 58.258639°W, datum WGS 84; elev. 199 m). The tadpoles were kept in captivity for later identification. However, one of the individuals (ABAM-H 612, SVL = 3.86 cm) developed one extra forelimb. For this reason, its growth was measured in different stages (Fig. 1). More studies should be performed to shed light on the scope, incidence, characteristics, and cause of anuran malformations (Meteyer 2000. Field Guide to Malformations of Frogs and Toads with Radiographic Interpretations. U.S. Department of the Interior, U.S. Geological Survey, National Wildlife Health Center. 18 pp.).

We are grateful to UFMT and ONF-Brazil for the logistic support. Thanks to FAPEMAT/CNPq for financial support and fellowship to JCN, LFB, and DJR, and ICMBio for allowing collection of specimens (nº 10174-1). This is publication 39 in the NEBAM technical series.

***NOTADEN BENNETTII* (Crucifix Frog). PEDAL LURING.** Prey luring behavior has been recorded in various squamate groups such as vipers, pythons, elapids, and skinks, as well as some cheloniids (Vitt and Caldwell 2013. Herpetology: An Introductory Biology of Amphibians and Reptiles. 4th ed. Academic Press, London. 757 pp.). In amphibians such as salamanders (Bavetz 1994. J. Herpetol. 28:504–506), pedal luring involves utilizing the toes and feet as the lures. Pedal luring has also been recorded in anurans, such as the terrestrial leptodactylid frog *Ceratophrys calcarata* (Murphy 1976. Herpetologica 32:339–341), the tree frog *Phyllomedusa burmeisteri* (Bertoluci 2002. Phyllomedusa 1:93), and possibly occurs in dendrobatids (Murphy 1976, *op. cit.*).

Notaden bennettii (Myobatrachidae) appears to also exhibit this behavior. We observed captive individuals kept at the Australian Museum (in Sydney) wiggling the tips of the fourth and fifth toes when they are in the proximity of prey. Both back feet were usually wiggled at the same time while the rest of the frog was immobile.

Although in the past apparent pedal luring was seen when the frogs were given ants, it was also seen in response to cricket prey. *Notaden bennettii* readily feeds on other small invertebrates, although ants are the main prey (Cogger 2001. Reptiles and Amphibians of Australia. New Holland/Reed, Sydney. 808 pp.). We recorded this behavior, which can be viewed at: http://www.youtube.com/watch?v=JujxVr2immk.

We thank Jodi Rowley for motivation and locating references and Jenifer Cork for video editing and uploading.

***PSEUDIS PLATENSIS* (Paradox Frog). PREDATION.** Amphibians are common prey for a great variety of vertebrates, arthropods, and even carnivorous plants (Duellman and Trueb 1986. Biology of Amphibians. McGraw-Hill, New York. 670 pp.; Pough et al. 1998. Herpetology. Prentice-Hall, New Jersey. 577 pp.). Known predators of *Pseudis platensis* are *Caiman yacare* (Santos et al. 1996. Herpetol. J. 6:111–117.), *Tigrisoma lineatum* (Prado 2003. Herpetol. Rev. 34:231–232), and *Guira guira* (Landgref Filho et

FIG. 1. *Pseudis platensis* being preyed on by *Hoplias* (*gr. malabaricus*) in Corumbá, Mato Grosso do Sul State, Brazil.

al. 2011. Herpetol. Rev. 42:90). At 1900 h on 26 May 2013, on the margin of a pond in the municipality of Corumbá, Mato Grosso do Sul State, Brazil (18.232492°S, 55.745097°W, datum: SAD 69), we observed *P. platensis* predation by *Hoplias* cf. *malabaricus* (Fig. 1). The diet of *Hoplias* is made up mostly of fishes (Lowe-McConnell 1975. Fish communities in tropical freshwaters: their distribution, ecology and evolution. Longman, London. 337 pp.), however, one study confirmed their predation on *Rhinella ornnata* (Haddad and Bastos 1997. Amphibia-Reptilia 18:295–298). This is the first record of *P. platensis* being consumed by *Hoplias*.

Aquidauana, MS, Brazil.

***RHINELLA CRUCIFER* (Sapo Cururuzinho; Striped Toad). HINDLIMB MALFORMATION.** The widespread occurrence of deformities of frogs has recently been perceived as a major environmental problem and should be reported in the scientific literature (Johnson et al. 2003. Cons. Biol. 17:1724–1737.). During a nocturnal survey on 10 July 2004, RBF collected a calling male of *Rhinella crucifer* (SVL = 63 mm) at the margin of a 3 × 3 m natural pond in the district of Alto Nova Almeida, municipality of Marechal Floriano, Espírito Santo state, Brazil (40.828208°W, 20.404561°S, datum WGS84; elev. 835 m). This specimen (MBML 7640) is deposited in the Zoological Collection of Museu de Biologia Mello Leitão, Santa Teresa municipality, Espírito Santo state, Brazil. This specimen has an abnormal right leg with a 3 mm outward curved, swollen, and calcified projection on the joint formation of its tibiofibula-tarsus (Fig. 1A). A radiography revealed that the right leg (27.3 mm) has a longer distal portion of its tibiofibula compared to the left leg (23.3 mm; Fig. 1B). It is likely that these anomalies originated during either embryonic or metamorphic stage of this *R. crucifer* due to the curvature of the distal portion of these bones. However this limb deformity did not prevent this specimen from reaching adulthood.

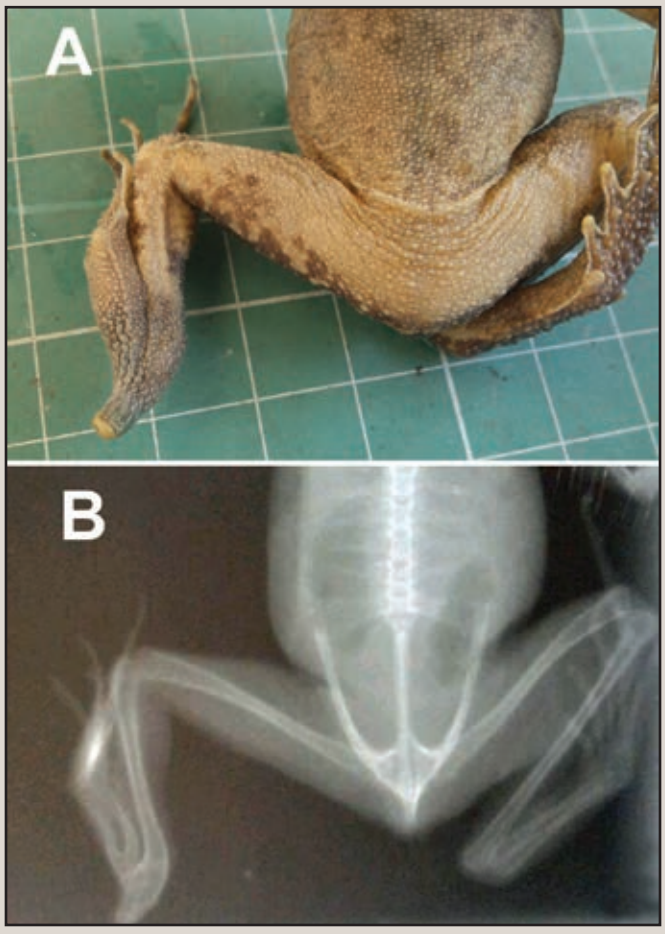

FIG. 1. Ventral view of an abnormal right limb of *Rhinella crucifer* from Espírito Santo state, Brazil. A) Photograph and B) radiograph.

We are grateful to João L. Rossi Jr. and Universidade Vila Velha for the radiography analysis of this specimen. RBF thanks Ecology Center at Utah State University for the financial support.

***TRACHYCEPHALUS TYPHONIUS* (Common Milk Frog). PREDATION.** Frogs are preyed upon by a great variety of invertebrates (Toledo 2005. Herpetol. Rev. 36:395–400), vertebrates (Centeno et al. 2010. Herpetol. Rev. 3:91–92), and even carnivorous plants (Duellman and Trueb 1994. Biology of Amphibians. Johns Hopkins University Press, Baltimore. 670 pp.). Herein, we describe an *in situ* observation of predation of a juvenile *Trachycephalus typhonius* (Hylidae) by the mantis *Stagmatoptera binotata* (Mantidae: Stagmatopterinae). At 0938 h on 18 March 2013, in a residence in the municipality of Santana, State of Amapá, Brazil (0.036311°N, 51.162481°W, datum WGS84; elev. 26 m), we observed the mantis holding the frog with its raptorial forelegs. The observations lasted 15–20 min. The mantis was an adult female measuring 68 mm. The role of mantis predation is well known in literature; however, reports of mantids preying upon anurans are scarce and only occasional (Pombal Jr. 2007. Rev. Bras. Biol. 24:841–843). Data here presented constitute the first record of *S. binotata* preying upon *T. thphonius*.

We are grateful to Cesar Augusto Favacho of Emilio Goeldi Paraense Museum for her help with the identification of the mantis.

TESTUDINES — TURTLES

***ACTINEMYS MARMORATA* (Western Pond Turtle). NEST PREDATION ASSOCIATION.** *Actinemys marmorata* is one of two native turtles in California, and a Species of Special Concern (Jennings and Hayes 1994. Amphibian and Reptile Species of Concern. California Department of Fish and Game, Sacramento, California. 255 pp.). This turtle also occurs in Oregon and Washington, where it is listed as critically sensitive and endangered, respectively. The species has experienced significant

habitat loss, alteration, and fragmentation over a majority of its range (Bury et al. 2012. Northwest Fauna 7:1–128). Habitat disturbances frequently occur in the uplands associated with the turtle's nesting habitat, limiting nest-site access and reducing recruitment rates. We report an additional confounding impact: an unexpected association between manmade infrastructure (fencing) and a high level of nest-site predation on a population of *A. marmorata*.

Moorhen Marsh, part of the Peyton Slough Marsh Complex, is a 21-acre constructed freshwater wetland owned and operated by the Mt. View Sanitary District (MVSD) in Martinez, California. Built in 1974, Moorhen Marsh is bordered by the Shell-Martinez Oil Refinery, MVSD's wastewater treatment plant, and Interstate 680 (Fig. 1). The marsh is managed by the MVSD primarily as habitat for native wildlife, including migratory birds and sensitive species, and for environmental education and research. *Actinemys marmorata* has been a focus of study on this site for several years, including efforts to determine the timing, location, and extent of nesting habitat. In the course of this study, we observed significant predation of recently constructed nests (predation was assumed based on excavated nests and empty and/or fragmented eggshells). A total of 18 predated turtle nests were found over a nearly two-month period (8 June–22 July 2013). Sixteen nests were determined to be those of *A. marmorata*; the other two were believed to have been made by *Trachemys scripta* (Red-eared Slider), a nonnative in California. All predated nests were located within 10 m of open water. Three *A. marmorata* nests were on a 3-m wide levee, within 1 m of the water's edge. A single *A. marmorata* nest was on a slope that borders the aquatic habitat and the treatment plant, within 5 m of the water. The remaining 12 *A. marmorata* nests and the two *T. scripta* nests (i.e., the great majority of predated nests) were found along the western and southern boundaries of the refinery's chain-link security fence that borders the project site (Fig. 1).

FIG. 1. Locations of predated Western Pond Turtle nests (red dots) within Moorhen Marsh, east of Martinez, California. Yellow dots indicate predated Red-eared Slider nests. Dashed blue line delineates chain-link boundary fencing.

We determined—through tracks, trails, direct observation, and camera stations—that the fence line was functioning to direct and concentrate potential predators along the western and southern borders of the marsh. Coincidentally, the fence impeded the upland extent to which *A. marmorata* could travel within the project site. Common use of the fence-line route by Red Fox (*Vulpes vulpes*), Gray Fox (*Urocyon cinereoargenteus*), Striped Skunk (*Mephitis mephitis*), Raccoon (*Procyon lotor*), and other species had created areas of patchy soil along the fence. This combination—open soil/grassland microhabitat, conditions ideal for turtle nesting—likely caused *A. marmorata* to nest in sites closely associated with predator pathways. Although we do not know the overall percentage of nests lost to predation, we observed the loss of 16 *A. marmorata* nests in 45 days. We speculate that approximately 30 adult female *A. marmorata* occupy the marsh; if our count is accurate, this attrition would represent a significant level of predation to nesting turtles on the site.

It appears clear that some barriers to movement (e.g., low-hanging chain-link fence) may be associated with increased predation events for nesting turtles. We recommend, when feasible, increasing the gap between fencing and the ground to allow turtles increased access to upland areas for nesting. If other barriers are constructed in the presence of turtle habitat, careful consideration should be given to reducing the potential for concentrated predation, particularly for declining species such as *A. marmorata*.

We thank Nicole Parizeau for constructive and helpful comments on the manuscript. We also thank the Mt. View Sanitary District for supporting this project and for access to the site.

Box 2757, Martinez, California 94553, USA (e-mail: KDavidson@mvsd.org); **SARAH M. FOSTER**, Foster Wildlife Surveys, 774 5th Ave., Sacramento, California 94818, USA (e-mail: aspetree@yahoo.com).

***APALONE FEROX* (Florida Softshell). TOLERANCE TO FIRE ANTS.** Many species of terrestrial reptiles are reported to have had fatal encounters with red imported fire ants (*Solenopsis invicta*) (Allen et al. 2004. Am. Midl. Nat. 152:88–103). The ants prefer disturbed areas in full to partial sun (Tschinkel 1988. Ann. Entomol. Soc. America 69:76–81), which coincides with preferred nesting habitat for many turtles (Ernst and Lovich 2009. Turtles of the United States and Canada. 2nd ed., Johns Hopkins Univ. Press, Baltimore, Maryland. 827 pp.). Hatchlings of numerous turtle species have fallen victim to fire ants, particularly once eggs have pipped (Landers et al. 1980. Herpetologica 36:353–361; Mount et al. 1981. J. Alabama Acad. Sci. 52:71–78; Conners 1998. Herpetol. Rev. 29:235; Buhlmann and Coffman 2001. J. Elisha Mitchell Sci. Soc. 117:94–100). Montgomery (1996. Bull. Chicago Herpetol. Soc. 31:105–106) reported several observations of adult *Terrapene carolina* killed by fire ants. Whiting (1994. Herpetol. Rev. 25:25) observed a *Pseudemys texana* female abandon her nest prematurely after being stung by about 150–200 fire ants, and Ferrell (2006. Herpetol. Rev. 37:343) observed a female *Trachemys scripta* abandon her nest with one egg after being stung by fire ants. In all of these cases, adults and nests were a meter or more away from nearby ant mounds. Here we report an observation of an *A. ferox* that tolerated numerous fire ant stings while nesting directly on a fire ant mound. On 17 April 2009, we observed an adult female (CL 385 mm, PL 304 mm, 5932

FIG. 1. Raised pustules from fire ant stings on the left inguinal area on a female *Apalone ferox*.

g) attempting to nest in a fire ant mound adjacent to a drainage impoundment on the Santa Fe College campus, Gainesville, Alachua Co., Florida, USA (29.680072°N, 82.436349°W; WGS 84). Numerous stings by the fire ants had accumulated on the skin of her head, forelimbs, and hindlimbs. Each sting formed the typical raised pustule commonly observed on humans after fire ant stings (Fig. 1). The female was in the process of laying her eggs but was caught before she completed the process and was returned to the pond after being measured. This is the first report of an *A. ferox* attempting to lay eggs in a fire ant mound (Meylan and Moler 2006. *In* P. A. Meylan [ed.], Biology and Conservation of Florida Turtles, Chelonian Res. Monogr. 3, pp. 160–168). We thank Matt Kail for help with this observation.

JOSEPH C. MITCHELL, P.O. Box 2520, High Springs, Florida 32655, USA (e-mail: dr.joe.mitchell@gmail.com); **GERALD R. JOHNSTON**, Department of Natural Sciences, Santa Fe College, Gainesville, Florida 32606, USA (e-mail: jerry.johnston@sfcollege.edu).

***APALONE SPINIFERA* (Spiny Softshell Turtle). CHELONIOPHAGY.** Turtles of the family Trionychidae are predominately carnivorous and known to consume a wide range of prey items. In the wild, some species (*Aspideretes gangeticus* and *Lissemys punctatus*) have been known to occasionally include turtles in their diets (Moll and Moll 2004. The Ecology, Exploitation and Conservation of River Turtles. Oxford University Press, New York. 303 pp.). Herein we present the first documentation of the Spiny Softshell as a cheloniophage. On 3 April 2010 at 1242 h in Leonhardt Lagoon, Dallas Co., Texas, USA (32.777428°N, 96.761484°W), an adult *Apalone spinifera* was photographed as it emerged from the water onto a basking surface. In its jaws was a hatchling Red-eared Slider (*Trachemys scripta elegans*) (Fig. 1). Ingestion was not observed, as the *A. spinifera* returned to the water, still holding its prey, within three minutes of its emergence. A photo voucher has been deposited at the University of Texas at Arlington Digital Collection UTADC 7649.

PHOTO BY JULIE COLLINS

FIG. 1. Adult *Apalone spinifera* holding a hatchling *Trachemys scripta elegans* in its mouth.

CARL J. FRANKLIN, Amphibian and Reptile Diversity Research Center, University of Texas Arlington, Arlington, Texas 76019, USA; e-mail: Franklin@uta.edu.

***APALONE SPINIFERA* (Spiny Softshell), *CHELYDRA SERPENTINA* (Snapping Turtle), and *STERNOTHERUS ODORATUS* (Eastern Musk Turtle). HOMING BEHAVIOR.** Homing ability (i.e., the ability of a species to return to a home range after being moved or displaced) has been reported in several freshwater turtle species, for example: *Chrysemys picta* (Cagle 1944. Univ. Michigan Mus. Zool. Misc. Publ. No. 61:1–34); *Terrapene ornata ornata* (Legler 1960. Univ. Kansas Publ. Mus. Nat. Hist. 11:527–669); *Graptemys pulchra* (Shealy 1976. Bull. Florida St. Mus. Biol. Sci. 21:47–111); *Trachemys scripta elegans* (Tucker and Lamer 2008. Chelon. Conserv. Biol. 7[1]:145–149); *Sternotherus odoratus* (Andres and Chambers 2006. Amer. Midl. Nat. 156:45–51; Smar and Chambers 2005. Southeast Nat. 4[3]:527–532; Williams 1952. Copeia 1952:76–82); and *Glyptemys insculpta* (Carroll 1978. Copeia 1978:117–126).

Little is known about the homing ability of *Apalone spinifera* and *Chelydra serpentina*. *A. spinifera* has been found to possess the orientation mechanisms required for long migrations (DeRosa and Taylor 1980. Behav. Ecol. Sociobiol. 7[1]:15–23; DeRosa and Taylor 1982. Copeia 1982:394–399). Female *C. serpentina* may undertake extensive nesting migrations, traveling 4–14 km away from their home range, often to sites upriver, but return to their original home range once nesting is completed (Obbard and Brooks 1980. Herpetologica 36[2]:158–162). To our knowledge, there are no published reports of *C. serpentina* demonstrating homing behavior after being released in an unfamiliar location.

In August and September 2010, as part of turtle rescue and recovery efforts following an oil spill affecting approx. 57 km of the Kalamazoo River in Calhoun and Kalamazoo counties, Michigan, USA, five adult *A. spinifera* (three males and two females), six adult *C. serpentina* (three males and three females), and five *S. odoratus* (three males and two females) were captured in the Kalamazoo River. Captures were made using a combination of hoop traps and hand collecting from multiple locations within the spill area. Turtles were cleaned of oil, implanted with a passive integrated transponder (PIT) tag, and released. Due to crude oil contamination at their original capture location, it was necessary to release turtles various distances from their original capture location in areas not affected by the oil. Release locations were chosen based on the presence of suitable habitat and distance from contamination. Each of the following turtles was subsequently recaptured and all exhibited presumed homing behavior.

Apalone spinifera.—An adult female *A. spinifera* (35.2 cm straight-line carapace length [SCL], 3800 g) was captured on 27 August 2010 (42.3046°N, 85.1363°W; NAD83) and housed overwinter in a wildlife rehabilitation facility. The turtle was

released on 12 May 2011 in the Kalamazoo River (42.2933°N, 85.1235°W), approximately 2.4 linear channel km from its original capture location. It was recaptured on 10 August 2011 in the Kalamazoo River (42.3062°N, 85.1384°W) approx. 1.9 linear channel km downstream of its release point and less than 0.5 linear channel km from its original capture location.

An adult male *A. spinifera* (16.5 cm SCL, 426 g) was captured on 27 August 2010 (42.3022°N, 85.1329°W) and released on 30 August 2010 in Rice Creek (42.2952°N, 84.8873°W), a small tributary of the Kalamazoo River, approximately 25.25 linear channel km from its original capture location. The turtle was recaptured on 23 June 2011 in the Kalamazoo River (42.3021°N, 85.1328°W), having traveled approx. 25.25 linear channel km downstream (8.0 linear channel km Rice Creek; 17.25 linear channel km Kalamazoo River) of its release point, crossing a 4.57 m retired hydroelectric dam, where it was recaptured less than 20 m from its original capture location.

An adult female *A. spinifera* (31.5 cm SCL, 2500 g) was captured on 29 August 2010 (42.3606°N, 85.2988°W) and released on 9 September 2010 in the South Branch of the Kalamazoo River (42.2028°N, 84.7945°W), approximately 64.5 linear channel km from its original capture location. The turtle was recaptured on 30 July 2011 in the Kalamazoo River (42.2703°N, 85.0618°W), having traveled approx. 37.5 linear channel km downstream of its release point and crossing three retired hydroelectric dams (2.12 m, 4.27 m, and 4.57 m respectively), where it was recaptured approx. 27 linear channel km from its original capture location.

An adult male *A. spinifera* (19.7 cm SCL, 632 g) captured on 2 September 2010 (42.3026°N, 85.1809°W) was released on 9 September 2010 in the South Branch of the Kalamazoo River (42.2028°N, 84.7945°W), approximately 48.8 linear channel km from its original capture location. The turtle was recaptured on 1 September 2011 in the Kalamazoo River (42.3045°N, 85.1481°W), having traveled approx. 45.4 linear channel km downstream of its release point and crossing three hydroelectric dams (2.12 m, 4.27 m, and 4.57 m respectively), where it was recaptured approx. 3.4 linear channel km from its original capture location. To our knowledge, this is one of the longest homing movements reported for a freshwater turtle in the United States.

Another adult male *A. spinifera* (17.2cm SCL, 432 g) was captured on 23 September 2010 (42.2725°N, 85.0658°W) and released on 24 September 2010 in the Kalamazoo River (42.2886°N, 85.4059°W), approximately 43.5 linear channel km from its original capture location. The turtle was recaptured on 12 July 2011 in the Kalamazoo River (42.3526°N, 85.2845°W) approx. 19.5 linear channel km upstream of its release point and approx. 24 linear channel km from its original capture location.

Apalone spinifera has been shown to move up to 13.7 km between activity areas (Galouis et al. 2002. J. Herpetol. 36(3):402–411). However, to our knowledge, this is the first report of presumed homing behavior. Three individuals reported here made movements of nearly two to three times the distance reported by Galouis et al. (*op. cit.*) (25.25 km, 37.5 km, and 45 km, respectively), representing to our knowledge the furthest reported movement of *A. spinifera*.

Chelydra serpentina.—An adult female *C. serpentina* (24.2 cm SCL, 3.8 kg) was captured on 26 April 2011 (42.3021°N, 85.1370°W; NAD 83) and released on 11 May 2011 in the Kalamazoo River (42.2932°N, 85.1235°W), approximately 2.1 linear channel km from its original capture location. The turtle was recaptured on 20 June 2011 in the Kalamazoo River (42.3062°N, 85.1384°W) approx. 2.0 linear channel km downstream of its release point and less than 100 m from its original capture location.

An adult male *C. serpentina* (39.5 cm SCL, 12.4 kg) was captured on 10 July 2011 (42.3058°N, 85.14571°W) and released on 20 July 2011 (42.3085°N, 84.1398°W), approximately 0.9 linear channel km from its original capture location. The turtle was recaptured on 16 September 2011 in the Kalamazoo River (42.3046°N, 85.1481°W) approx. 0.7 linear channel km downstream of its release point and approx. 200 m from its original capture location.

An adult male *C. serpentina* (31.0 cm SCL, 7.1 kg) was captured on 18 August 2010 (42.2699°N, 85.0614°W) and an adult female (28.5 cm SCL, 6.0 kg) was captured on 2 October 2010 (42.2702°N, 85.0611°W), approx. 40 m from where the male caught on 18 August had been captured. Both turtles were released on 12 May 2011, approx. 2.0 linear channel km from their original capture locations (42.2742°N, 85.0813°W). Both turtles were recaptured on 2 August 2011 in the same trap in the Kalamazoo River (42.2728°N, 85.0660°W), approx. 1.9 km upstream from their release point and less than 200 m from their original capture locations.

An adult male *C. serpentina* (28.5 cm SCL, 5.2 kg) was captured on 21 September 2010 (42.2927°N, 85.1205°W) and an adult female (23.0 SCL, 3.1 kg) was captured on 22 September 2010 (42.3361°N, 85.2272°W). Both were released on 27 September 2010 in the same location in the Kalamazoo River (42.3357°N, 85.3455°W), approx. 29.4, and 15.5 linear channel km, respectively, from their original capture locations. Both turtles were recaptured on 18 July 2011 in the Kalamazoo River in the same trap (42.2863°N, 85.4083°W), approx. 9.5 linear channel km downstream from their release point. Both turtles traveled the "wrong" direction from their original capture location; however, it appeared they both traveled together downstream. To our knowledge, this is the first report of both sexes of *C. serpentina* apparently moving a long distance together.

Although *C. serpentina* exhibits some degree of natal homing ability, prior to this note no examples of homing ability from relocation have been reported. Female *C. serpentina* have been known to migrate great distances to nest. Obbard and Brooks (*op. cit.*) reported one individual traveled 16 km round trip. Two individuals reported here (one male and one female) traveled approximately 9.5 km, representing to our knowledge the furthest reported movement of *C. serpentina* not associated with nesting.

Sternotherus odoratus.—An adult male *S. odoratus* (11.1 cm SCL, 158 g) was captured on 21 September 2011 (42.2668°N, 85.0536°W; NAD83) and was housed overwinter in a wildlife rehabilitation facility. The turtle was released on 12 May 2011 in the Kalamazoo River (42.2933°N, 85.1235°W), approximately 6.3 linear channel km from its original capture location. It was recaptured on 26 August 2011 in the Kalamazoo River (42.2701°N, 85.0623°W) approx. 5.6 linear channel km upstream of its release point and less than 0.7 linear channel km from its original capture location.

An adult female *S. odoratus* (10.1 cm SCL, 181 g) was captured on 14 October 2010 (42.2702°N, 85.0610°W) and was housed overwinter in a wildlife rehabilitation facility. The turtle was released on 12 May 2011 in the Kalamazoo River (42.2743°N, 85.0813°W), approximately 2.1 linear channel km from its original capture location. It was recaptured on 1 September 2011 in the Kalamazoo River (42.2703°N, 85.0618°W) approx. 2.0 linear channel km upstream of its release point and less than 60 m from its original capture location.

An adult male *S. odoratus* (10.6 cm SCL, 170 g) was captured on 6 October 2010 (42.3494°N, 85.2688°W) and released on 8 October 2010 in the Kalamazoo River (42.3504°N, 85.2759°W), approximately 0.7 linear channel km from its original capture location. The turtle was recaptured on 10 October 2010 in the Kalamazoo River (42.3494°N, 85.2683°W) approx. 0.67 linear channel km upstream of its release point and less than 30 m from its original capture location.

An adult male *S. odoratus* (11.2 cm SCL, 200 g) was captured on 17 October 2010 (42.2769°N, 85.0680°W) and was housed overwinter in a wildlife rehabilitation facility. The turtle was released on 11 May 2011 in the Kalamazoo River (42.2743°N, 85.08133°W), approximately 1.2 linear channel km from its original capture location. It was recaptured on 30 August 2011 in the Kalamazoo River (42.2702°N, 85.0610°W) approx. 2.0 linear channel km upstream of its release point and 0.8 linear channel km from its original capture location. Although close to its original capture location, this turtle moved 1.2 km past its original capture location before recapture.

An adult female *S. odoratus* (9.9 cm SCL, 168 g) was captured on 14 October 2010 (42.2702°N, 85.0610°W) and was housed overwinter in a wildlife rehabilitation facility. The turtle was released on 12 May 2011 in the Kalamazoo River (42.2743°N, 85.0813°W), approximately 2.1 linear channel km from its original capture location. The turtle was recaptured on 1 September 2011 in the Kalamazoo River (42.2957°N, 85.1242°W). It had traveled downstream approximately 6.7 linear channel km from its release point and approximately 4.6 linear channel km past where it was originally captured.

Three previous studies (Williams, *op. cit.*; Smar and Chambers, *op. cit.*; Andres and Chambers, *op. cit.*) all conducted in lentic habitats (lakes, ponds), demonstrate the homing ability and site philopatry of *S. odoratus* at average distances of about 200–1100 m. To our knowledge no previous reports discussed movements or homing abilities of *S. odoratus* in lotic habitats. Two individuals reported here (one male and one female) traveled approximately 6.7 and 5.6 linear channel km, respectively, representing to our knowledge the furthest reported movement of *S. odoratus*.

We thank Enbridge Inc. for providing funding for the turtle rescue and recovery efforts that provided data for this note. We thank our co-workers, Chris Tabaka, Robert Doherty, Luke Hodges, 22 Stantec biologists, Focus Wildlife, and volunteers who assisted with turtle recovery, cleaning, and release.

***CHRYSEMYS PICTA PICTA* (Eastern Painted Turtle). LORDOSIS.** The most commonly reported morphological malformation of the spine in freshwater turtles is kyphosis. Most cases involve vertebrals 2 or 3 resulting in a dorsally convex hump of varying sizes on the carapace (Rhodin et al. 1984. Brit. J. Herpetol. 6:369–373; Tucker et al. 2007. Herpetol. Rev. 38:337; Iverson 2007 Herpetol. Rev. 38:334). The frequency of occurrence of kyphosis in natural populations, however, is low with a range of < 0.1–0.5% in sea turtles (Rhodin et al. 1984, *op. cit.*) and 0.004–2.56% in freshwater turtles (J. Iverson, pers. comm.). The opposite of kyphosis is lordosis ("sway-back"). This is a concave deformity of the spine in the sagital plane at the approximate middle of the carapace (Rhodin et al. 1984, *op. cit.*). Previous cases of chelonian lordosis have been reported only for sea turtles. This

FIG. 1. A male *Chrysemys picta picta* from an urban lake in Henrico County, Virginia with lordosis.

malformation occurs in *Caretta caretta*, *Chelonia mydas* (or *Eretmochelys imbricata*, identification unclear), and *Lepidochelys olivacea* (Deraniyagala 1939. The Tetrapod Reptiles of Ceylon. Vol 1. Testudines and Crocodilians. London; Rhodin et al. 1984, *op. cit.*; Glazebrook and Campbell 1990. Diseases Aquat. Org. 9:83–95; Kochinsky et al. 1995. Herpetopathologia 2:105–120; Oros et al. 2005. Diseases Aquat. Org. 63:13–24). All observations have been of single individuals in samples ≥ 93. A thorough review of shell malformations in turtles is in Rothschild et al. (2013. *In* Brinkman et al. [eds.], Morphology and Evolution of Turtles, pp. 501–534. Springer Publ. Co., New York) but he only notes the lordosis cases in Rhodin et al. (1984, *op. cit.*). On 24 August 1979, I captured an adult male *C. p. picta* (77 mm CL, 75 mm PL, 65 g) in an urban pond in Henrico Co., Virginia, USA, with lordosis (Fig. 1). This turtle was part of a study of the population ecology of *C. picta* and *Sternotherus odoratus* and was the only turtle with this type of malformation in 818 *C. picta* marked during 1979–1981 (Mitchell 1988. Herpetol. Monogr. 2:40–61). The male was marked and released but never recaptured. This may be the only case of lordosis in freshwater turtles reported to date.

I thank John Iverson for reviewing the manuscript and his help with literature.

JOSEPH C. MITCHELL, P.O. Box 2520, High Springs, Florida 32655, USA; e-mail: dr.joe.mitchell@gmail.com.

***CHRYSEMYS PICTA* (Painted Turtle) and *CHELYDRA SERPENTINA* (Snapping Turtle). INTERSPECIFIC INTERACTIONS.** A recently reported case of commensalism between *Chrysemys picta* and *Chelydra serpentina* involved the former feeding on scraps of food made available by the latter (Himes 2013. Herpetol. Rev. 44:501). Other reported interactions between these species include predation by *Chelydra* on *Chrysemys* (Ernst and Lovich 2009. Turtles of the United States and Canada, 2nd ed. Smithsonian Institution Press, Washington, D.C. 827 pp.), an apparently mutualistic cleaning symbiosis by which *Chrysemys* removed algae and leeches from *Chelydra* (Krawchuk et al. 1997. Can. Field-Nat. 111:315–317), and the use of *Chelydra* for basking by *Chrysemys* (Legler 1956. Trans. Kansas Acad. Sci. 59:461–462). We observed additional interactions between *Chrysemys* and *Chelydra* in Brown Co., Wisconsin during the summer of 1991 in a stretch of the Suamico River that was mostly shallow and partially shaded by riparian forest. A high steep bank above one of the few relatively deep pools in the river (> 1.5 m deep and 22 m across when measured during a period of low water) provided a vantage point to observe the following: 6 June, 1245 h – large *Chelydra* basking on dead floating tree entered water, swam to another downed tree, and climbed up to bask without disturbing two *Chrysemys* already basking; 11 June, 1215 h – large *Chelydra*

attempted four times to climb floating log to bask but rolled it over, each time tumbling two basking *Chrysemys* into water; 1320 h – two *Chrysemys* underwater with mouths near hind legs of large *Chelydra*, sometimes appearing to make contact with their mouths (possibly removing algae or leeches?); later same afternoon (time not recorded) – large *Chelydra* basking at surface (submerged) with adult *Chrysemys* basking (partly submerged) on rear of its carapace; second *Chrysemys* tried unsuccessfully to climb on *Chelydra*; 13 June, 1410 h – large *Chelydra* at surface (submerged) with large *Chrysemys* basking (partly submerged) on posterior of carapace, oriented perpendicular to *Chelydra*; after ~ 2 min, *Chrysemys* fell off when *Chelydra* began swimming slowly upstream. As many as five *Chrysemys* were observed in the pool at the same time on some occasions, and as many as two *Chelydra*, so we cannot be sure that it was the same turtles that we observed interacting on each occasion. As noted by Himes (2013, *op. cit.*), *Chrysemys* associating with *Chelydra* may stay to their rear to avoid predatory attacks. In addition to basking on *Chelydra*, *C. picta* have been reported by Gelatt and Kelley (1995. Can. Field-Nat. 109:456–458) basking on a nesting loon (*Gavia immer*).

Our field work was funded by grants from the Chicago Herpetological Society and the Saint Norbert College Student-Faculty Endowment Fund.

***DEIROCHELYS RETICULARIA CHRYSEA* (Florida Chicken Turtle). KYPHOSCOLIOSIS.** Freshwater turtle populations occasionally include a small percentage of individuals with kyphosis or, even more rarely, scoliosis. Most of the cases reported have been on species of cryptodires, although a few have been published for pleurodires (Plymale et al. 1978. Southwest. Nat. 23:457–462; Trembath 2009. Chelonian Cons. Biol. 8:94–95; Rothschild et al. 2012. Herpetological Osteopathology. Springer Science, New York. 550 pp.; J. B. Iverson, pers. comm.). Only a few cases of scoliosis have been reported. Rhodin et al. (1984. British J. Herpetol. 6:369–373) stressed the need for accurate terminology and coined the term kyphoscoliosis for turtles that have both types of deformities. There has been only one report of kyphosis for *D. reticularia*, by Mertens (1940. Senckenbergiana 22:236–243), who noted the condition in a captive individual but gave no additional information.

We captured an adult female *D. reticularia chrysea* with kyphoscoliosis in a small pond on the urban Santa Fe College campus in Gainesville, Alachua Co., Florida, USA (Fig. 1). She was captured three times between 2009 and 2013. Measurements taken at each capture (24 May 2009 – CL = 159 mm, PL = 135 mm, mass = 725 g; 1 March 2010 – CL = 172 mm, PL = 145, mass = 897 g; 19 April 2013 – CL = 187 mm, PL = 157 mm, mass 1177 g) demonstrate what appears to be a normal pattern of growth of 10 mm PL for the first year and an average of 4 mm PL annually during the subsequent three years. This pattern is similar to that reported for *D. reticularia* in South Carolina (Buhlmann et al. 2009. Herpetologica 65:39–53). Growth in turtles with kyphosis appears to be similar to growth in individuals in the same population lacking this deformity (Selman and Jones 2012. Chelon. Conserv. Biol. 11:259–261). Scoliosis is evident in the posterior half of the animal. The vertebral midline starts to curve to the right at the posterior third of the second vertebral scute and then curves slightly left starting at the suture between the third and fourth vertebral scutes (Fig. 1). All but the first vertebral scute are deformed. The pleural scutes on the right are larger than those on the left, suggesting that the right side grew faster than the corresponding scutes on the left side during embryonic growth. The process of premature and asymmetrical fusion of thoracic vertebrae that results in disproportionate shell growth described by Rhodin et al. (*op. cit.*) may apply to the *D. reticularia* described here.

FIG. 1. Lateral and dorsal views of female *Deirochelys reticularia chrysea* from Alachua Co., Florida, with kyphoscoliosis.

We thank John Iverson for providing the Mertens citation and comments on the manuscript.

***EMYDOIDEA BLANDINGII* (Blanding's Turtle). MASS MORTALITY.** Mass mortality of freshwater turtles as a result of controlled, accidental, or natural wetland drying and/or drawdown is uncommon, or under-reported in the literature (but see Hall and Cuthbert 2000. Chelon. Conserv. Biol 3[4]:643–649). Here we report mass mortality of *Emydoidea blandingii* in a shallow, 90-ha rich fen where water outflow is uncontrolled; outflow is via several shallow, slow-moving stream channels, and water levels

FIG. 1. A) Intact shell, weathered, found on dry land. B) Typical placement of turtle shells near edge of open water habitat.

and flow are generally dictated by snowmelt and rainfall accumulation.

Misery Bay Provincial Park is a 760-ha Nature Reserve on the south side of Manitoulin Island, Ontario, Canada, on the north shore of Lake Huron (45.800503°N, 82.726107°W). The park is characterized by limestone alvar and patterned fen over limestone pavement, as well as fine sand beach, a key-hole bay, ephemeral wetlands, streams, and mixed-wood forest. Development surrounding the park is relatively limited, and includes one farm property (hay fields), one low-use two-lane highway, and a few cottages/cottage roads.

In a May 2012 field visit to Misery Bay, 13 Blanding's Turtles, three Painted Turtles (*Chrysemys picta)*, and evidence (tracks) of one Snapping Turtle (*Chelydra serpentina*), were observed in a small fen and in a vernal pond. All observations were made in roadless areas generally not used or accessed by park visitors. No turtle mortality was observed at this time, and no further visits were made in 2012.

During May and June 2013, target wetlands were searched weekly for Blanding's Turtles. Areas searched included three distinct wetlands totalling less than 75 ha: two fens and a wet beach with connecting tributaries totalling 30 ha, 16 ha, and 25 ha, respectively. Also searched was one 0.8-ha vernal pond adjacent to but hydrologically separate from the fen/beach system, and two isolated vernal ponds (1.5 km from the fen/beach), averaging 0.6 ha each. Thirty-two individual turtles were encountered during the search period, including 29 Blanding's Turtles, two Snapping Turtles, and one Painted Turtle. Regular bi-weekly and monthly searches and tracking continued between July and October 2013, during which the entire 90 ha of fen was searched.

In addition to over 30 living turtles, 59 dead turtles (49 Blanding's Turtles and 10 Painted Turtles) were found in the two adjoining fen areas of the park. Nearly all dead turtles were found on the edges of shallow ponds and streams, in graminoids and/or at the base of shrubs. Few turtle remains were found in open water (shallow fen ponds). All remains appeared weathered: little to no soft tissue remaining, small amounts of moss or algae growing on scute seams and surfaces, and some or no keratin peeling or falling off (depending on exposure to water). Carapace and plastron condition varied: shells were either intact, separated, broken into pieces, or missing parts. There were no obvious signs of predation (i.e. bite marks on the carapace or plastron). Park staff and visitors also reported three (additional) dead turtles on the beach or just north of the beach in late summer 2012. The condition of these three additional dead turtles was as follows: one adult Painted Turtle desiccated but otherwise intact, one adult Blanding's Turtle "picked clean," and one adult Blanding's Turtle recently dead with predator bites on the neck and a missing hind limb. The weathering and condition described above suggests the turtles did not die over the winter 2012/2013, but sometime earlier. All but eight of the 51 dead Blanding's Turtles were adults; of the 62 known dead turtles, 20 were female, 13 were male, and 29 were of unknown sex (including 10 Painted Turtles, 16 Blanding's Turtles missing plastron sections or too young to sex, and the three reported visitor observations).

Nearly all living turtles, and all dead turtles, were observed in areas not normally accessed by park visitors. Water conditions in the fen in much of 2012 are unknown, but unseasonal drought conditions may have contributed to this mortality event. Low water levels in a normally shallow fen may have resulted in a reduction in suitable foraging, cover and hibernation habitat, and increased predator access. No turtle mortality was observed in the three ephemeral ponds, though they were searched with equal effort.

Blanding's Turtles are at risk throughout almost all of the species' North American range; in Ontario, the species is considered Threatened (Ontario Regulation 230/08 s.3). The Misery Bay Blanding's Turtle population is found in a relatively pristine, protected natural environment, where the typical threats of road mortality, habitat loss, and illegal harvesting/collection are minimal or virtually absent. However, mass mortality events such as was described above can have long-lasting negative effects on even the most protected of populations (Congdon et al. 1993 Conserv. Biol 7:826–833; Brooks et al. 1991. Can. J. Zool. 69:1314–1320).

At present Ontario Parks is monitoring the movements of six turtles in the park using radio telemetry, but qualified outside researchers are welcome to carry on or supplement this study. Please contact the author for more information about conducting research in Ontario's protected areas.

ANNA C. SHEPPARD, Ontario Parks (Northeast Zone), 199 Larch Street, Suite 404, Sudbury, Ontario P3E 5P9, Canada; e-mail: anna.sheppard@ontario.ca.

FRESHWATER TURTLE SPECIES. PREDATION. Shively et al. (2011. Herpetol. Rev. 42:423) reported on turtle shells found beneath a Bald Eagle (*Haliaeetus leucocephalus*) nest near the shore of Kincaid Lake, Rapides Parish, Louisiana, USA. On 24 July

PHOTO BY BY S. SHIVELY

FIG. 1. Skeletal remains of turtles and catfish found beneath Bald Eagle nest.

PHOTO BY S. SHIVELY

FIG. 2. Bald Eagle nest with skeletal remains of catfish and turtles visible.

2013, I climbed the Loblolly Pine (*Pinus taeda*) of this nest tree to install video surveillance cameras above the nest, 30.5–33.5 m above the ground. Here I report on additional turtle and fish remains found in and under the nest.

A search around the base of the nest tree yielded the skeletal remains of turtles of three species along with six Flathead Catfish (*Pylodictus olivaris*). The turtles included 17 *Sternotherus carinatus*, four *Graptemys pseudogeographica kohnii*, and four *Apalone* sp. The *S. carinatus* were mostly adults measuring 10–13 cm in carapace length, the *G. p. kohnii* were mostly large juveniles or young adult males measuring 13–15 cm in carapace length, and the *Apalone* sp. were mostly juveniles measuring 15–18 cm in carapace length. The largest catfish skull appeared to be from a fish approximately 60 cm in total length.

A search of the nest itself yielded a similar assemblage of turtle shells and catfish skulls, scattered throughout the visible portion of the nest, with individual shells/skulls being tucked into pockets in the sticks comprising the nest. There were many more shells and skulls in the accessible part of the nest than was found on the ground, but the proportion of each species was roughly the same in the nest as on the ground.

Turtles are known prey of Bald Eagles feeding young. Clark (1982. J. Field Ornithol. 53:49–51) reported that over a five-year period 25% of successful bald eagle nests examined in the Chesapeake Bay region contained turtle shells and that four turtle species were involved. But at least two of the three turtle species preferred by the Kincaid Lake eagles are not necessarily what would be expected based on the species most often seen basking on logs around the lake shore. The most common basking turtles around Kincaid Lake are *Pseudemys* sp. and *Trachemys scripta elegans* followed by *G. p. kohnii*. *Apalone* sp. are only occasionally seen basking and *S. carinatus* rarely bask. That might suggest that the eagles are not catching the turtles while basking. Jeff Boundy, herpetologist for Louisiana Department of Wildlife and Fisheries, (pers. comm.) suggests that *S. carinatus* appear to forage unwarily in shallow clear water, rendering them more vulnerable to predation. The size and shapes of the turtle species taken may also make them preferred targets for the eagles. Smaller turtles are more easily encompassed by the eagles' talons than are larger turtles and, obviously, are lighter and more easily carried. The shells of both *S. carinatus* and *G. p. kohnii* have a pronounced mid-dorsal ridge which might make it easier for the eagles' talons to grasp, as opposed to the smoothly rounded carapaces of *Pseudemys* and *Trachemys*. Softshells are probably easily gripped by the sharp talons. Another possible factor influencing turtle species selection may be ease of picking flesh out of the shell. *S. carinatus* have relatively small plastra, which leaves more of their legs, neck, and tail exposed.

STEVE SHIVELY, Calcasieu Ranger District, Kisatchie National Forest, 9912 Hwy 28 West, Boyce, Louisiana 71409, USA; e-mail: steveshively@fs.fed.us.

***GRAPTEMYS BARBOURI* (Barbour's Map Turtle). BASKING HEIGHT.** Many freshwater turtles aerially bask on emergent rocky and woody substrate, which is hypothesized to facilitate thermoregulation and to discourage ectoparasites and algal growth (Boyer 1965. Ecology 46:99–118). Basking sites are often limited and can subsequently elicit aggressive competitive behaviors within some turtle species (Lindeman 1999. J. Herpetol. 33:214–219). Many species choose basking sites that extend over water, presumably to increase exposure to light and to allow quick escape from potential predators. Boyer (1965, *op. cit.*) noted a tendency for turtles of the family Emydidae (especially *Graptemys* spp.) to attempt to achieve the highest possible elevation on a chosen basking site.

At 1625 h on 14 August 2013, we observed an adult female *G. barbouri* basking on a leaning Bald Cypress (*Taxodium distichum*) snag over Spring Creek (~7.5 km N of Smith's Landing; 30.94679°N, 84.74577°W) in the Lower Flint River Basin, Decatur Co., Georgia, USA. The turtle was photographed just before it retreated into the water (Fig. 1). Upon measurement, the turtle was found to have been basking 1.9 m above the surface of the water. One end of the snag was anchored on shore; no other turtles were observed on this basking site.

As far as we know, this is the highest vertical basking location noted for *G. barbouri*. Some riverine turtle species, such as *Sternotherus minor* (Loggerhead Musk Turtle), are known for their climbing ability, although fewer reports exist for larger species such as map turtles (Ernst and Lovich 2009. Turtles of the United States and Canada, 2nd ed. Johns Hopkins Univ. Press, Baltimore, Maryland. 827 pp.). A smaller map turtle species, *G. flavimaculata* (Yellow-blotched Map Turtle), has been found to bask as high as 3.7 m above water (Floyd 1973. Int. Tortoise

FIG. 1. An adult female *Graptemys barbouri* basking at a probable record height on Spring Creek in the Lower Flint River Basin, Decatur Co., Georgia.

FIG. 2. Presa La Galera, located in the Municipality of Abasolo, Guanajuato, Mexico.

Turtle Soc. J. 7:8–10). In contrast, Flaherty and Bider (1984. Am. Midl. Nat. 111:259–266) found the average basking sites of *G. geographica* (Northern Map Turtle) to be just 0.2 m above the water's surface. Vogt (1981. Natural History of Amphibians and Reptiles of Wisconsin. Milwaukee Public Museum, Milwaukee, Wisconsin. 205 pp.) noted that map turtles (referring to *G. geographica*) will bask 2–5 m above the water surface and "pose an ominous threat to a canoeist's head."

JENSEN**, Georgia Department of Natural Resources - Nongame Conservation Section, Forsyth, Georgia 31029, USA; **BRIAN FOLT**, Department of Biological Sciences, Auburn University, Auburn, Alabama 36849, USA.

***GRAPTEMYS VERSA* (Texas Map Turtle). PREDATION ATTEMPT.** Large catfish are consumers of a wide range of vertebrate and invertebrate prey items. Herein we present the first documentation of a predatory attempt on a *Graptemys versa* by a large Flathead Catfish (*Plyodictus olivaris*). On 10 July 2013 at 2143 h ca. 8 miles W of Menard at the San Saba River, Menard Co., Texas, USA (30.90058°N, 99.91545°W; 602 m elev.), an adult male *G. versa* was observed being attracted to a fishing line baited with a dead minnow in 1.2 m of water. As the turtle bit into the bait it was slowly brought to the surface whereupon a large *P. olivaris* arrived and began to swallow the turtle. The rear quarter of the turtle was drawn partially into the mouth of the catfish before it was suddenly expelled. The expulsion of the turtle may have been prompted by two high intensity flashlights being directed towards the face of the fish. Neither the fish nor turtle were captured. We note that the mouth of the catfish had opened to a gape greater than the length of the turtle.

CARL J. FRANKLIN, Amphibian and Reptile Diversity Research Center, University of Texas Arlington, Arlington, Texas 76019, USA (e-mail: Franklin@uta.edu); **ANDREW BRINKER**, Biology and Environmental Science, R. L. Paschal High School, 3001 Forest Park Boulevard, Fort Worth, Texas 76110, USA.

***KINOSTERNON INTEGRUM* (Mexican Mud Turtle). MORTALITY.** Currently there is little information on the ecology of many Mexican freshwater turtles, including mud turtles in the genus *Kinosternon* (Canseco-Márquez and Gutiérrez-Mayén 2006. Anfibios y Reptiles del Valle de Tehuacán-Cuicatlán, CONABIO, México, D.F., xvi + 302 pp.). Even less is known regarding the direct effects of human related activities on the habitats used by these species (Ramirez-Bautista et al. 2009. Herpetofauna del Valle de México: Diversidad y Conservación, CONABIO, México, D.F., xxiv + 213 pp.). In one report, pollutants were detected in water bodies inhabited by *K. scorpioides*. The pollutants, attributed to home and industrial sewage discharges, were believed to be among the factors that consequently triggered disease and increased mortality in these turtles (Sampedro-Marin et al. 2012. Rev. Colombiana Sci. Anim. 4:69–88). However, with respect to *K. integrum*, to date there are no reports on fatalities related to pollution in waters they inhabit.

On 1 February 2012, between 1130 and 1600 h, we found 23 individuals of *K. integrum* (Fig. 1) scattered on the shores of the Presa La Galera reservoir (Fig. 2), which is located in the Municipality of Abasolo, Guanajuato, Mexico (2228407.17°N, 233882.16°W, WGS84; elev. 1689 m). Nineteen turtles were represented by empty shells (KiPG5-GTO-FEB-2012 to KiPG23-GTO-FEB-2012), while four shells still contained soft body parts (KiPG1-GTO-FEB-2012 [length and width of carapace "LW"= 152 × 106 mm], KiPG2-GTO-FEB-2012 [LW= 105 × 79 mm], KiPG3-GTO-FEB-2012 [LW= 129 × 103 mm], and KiPG4-GTO -FEB-2012 [LW= 16 × 12 mm]). This mortality may be related to the contaminated water discharged by a brick factory located on land next to Presa La Galera. The brick factory uses discarded car tires

as the main fuel in the brick baking process, and consequently various pollutants end up in the waste water. We suspect that the chemical wastes discharged by this factory could very likely be the main cause of noted mass mortality of *K. scorpioides* in Presa La Galera (Badii-Thabet et al. 2005. CULCyT 2:4–20; Sampedro-Marin et al. 2012, *op. cit.*). More detailed studies are critically needed to determine the impact of this brick factory and its specific contaminants on this turtle population. All specimens (KiPG1-GTO-FEB-2012 to KiPG23-GTO-FEB-2012) are deposited in the Colección Herpetológica de la Estación Biológica del Instituto Tecnológico Superior de Irapuato.

Special thanks to J. D. Johnson for draft improvement and to S. Arguelles-Marmolejo for help in the field.

***KINOSTERNON SONORIENSE* (Sonoran Mud Turtle). WINTER MORTALITY.** Flash floods can have devastating impacts on biota in desert streams (Fisher et al. 1982. Ecol. Monogr. 52:93–110; Grimm and Fisher 1989. J. N. Am. Benthol. Soc. 8:293–307; Crandall et al. 2003. Comm. Ecol. 4:225–232). In particular, flash floods can pose substantial risks to Sonoran Mud Turtles that frequently inhabit perennial and ephemeral streams and impoundments throughout the Sonoran and Chihuahuan deserts. Although some freshwater turtles experience overwintering mortality due to the inability to cope with extreme temperature fluctuation (Cagle 1950. Ecol. Monogr. 20:32–54; Metcalf and Metcalf 1979. Herpetologica 35:93–96; Christiansen and Bickham 1989. J. Herpetol. 23:91–94), little is known about the risks Sonoran Mud Turtles encounter while overwintering. Mortality rates in adult turtles are often relatively low and constant compared to those of juveniles (Gibbons and Semlitsch 1982. J. Anim. Ecol. 51:523–527; Iverson 1991. Can. J. Zool. 69:385–391; Stone 2001. Southwest Nat. 46:41–53), but sporadic increases in mortality rates of adults or juveniles can influence population stability (Brooks et al. 1991. Can. J. Zool. 69:1314–1320; Congdon et al. 1994. Amer. Zool. 34:397–408; Buhlmann et al. 2009. Herpetologica 65:39–53).

From 16–25 March 2013, we collected 14 *Kinosternon sonoriense* carcasses (10 adult females, one adult male, and three juveniles) in the Peloncillo Mountains, Hidalgo Co., New Mexico, USA (31.483°N 109.017°W, WGS84; elev. 1726 m). The area is characterized by narrow canyons containing highly ephemeral and flood-prone streams separated by rugged mountain ridgelines. Some canyons also have impoundments constructed during the 1930s. Dead *K. sonoriense* were salvaged from two impoundments, BW Tank and BH Tank, located in different drainages, ca. 7 km apart. All turtles were previously marked in conjunction with an on-going mark/recapture study (Stone, *op. cit.*). During 17–22 March 2013, we found two adult female and three juvenile *K. sonoriense* carcasses at BW Tank. The adults were floating in the impoundment and the juveniles were found immediately downstream of the impoundment dam. On 18–19 March 2013, nine dead adult *K. sonoriense* (eight female and one male) were found at BH Tank, six were discovered on the bank and three were found just downstream from the impoundment dam. Nearly all carcasses were in the same state of decomposition with scutes still in place, shells intact, and no signs of predation. We also collected several other vertebrate carcasses; six Green Sunfish (*Lepomis cyanellus*) were found 10 m below BH Tank and three dead lizards (*Sceloporus virgatus, S. jarrovii,* and *Aspidoscelis neomexicana*) were found in canyon pools within the study area.

In the two weeks prior to sampling, the study area experienced several hard freezes and a flash flood. Temperature recorders (LogTag® TRIX-8) set throughout study area recorded freezing temperatures until 5 March 2013 (min = -1.7°C), then no recorded freeze until 9 March 2013 (min = -0.2°C). During 5–7 March 2013, daytime highs reached 25.4°C. On 7 March 2013, there was a major rainfall, producing heavy flow in the canyons (M. Carrier, pers. comm.) and signs of flooding were evident at the sites during sampling. During 9–15 March 2013 temperatures fell below freezing every day (min = -5.7°C) and daytime highs reached 29.5°C.

We have marked 79 adult female turtles at BH Tank since 2007 and have not captured an unmarked female there since May 2008. The individuals found dead in March 2013 represent ~10% of the marked adult females in this population. Chronic winter mortality at that level is unsustainable. Necropsied adults from BW Tank showed no signs of malnutrition, disease, or trauma to the shell, skeleton, or lungs, and both had maturing follicles of various sizes in the reproductive tract. The lack of blunt trauma and absence of water in lungs of the necropsied turtles indicates that death was not a direct result of flooding or drowning. However, flooding could have displaced turtles, exposing them to freezing. We hypothesize that a series of warm days caused turtles to move out of secure wintering sites, and then flash flooding followed by several hard freezes may have been the cause of the mortality.

All collected specimens were deposited in the University of Central Oklahoma Natural History Museum (UCONHM): Herpetology - *K. sonoriense* (UCO 1806, 1807, 1809–1820), *S. virgatus* (UCO 1805); Ichthyology - *L. cyanellus* (UCO 63).

We thank M. Gault, M. Carrier, and the MidBar Ranch for site access and weather information, K. Bliss, I. Sidor, and the New Hampshire Veterinary Diagnostics Laboratory (NHVDL) for necropsy data, K. Locey and B. Benson for field assistance, and J. Congdon for reviewing the manuscript. We thank the Office of Research and Grants at the University of Central Oklahoma for financial support. This study was conducted under permits issued by the New Mexico Department of Game and Fish (Permit No. 2905) and the U.S. Forest Service (Authorization ID: SUP0800-02) and under an IACUC protocol from the University of Central Oklahoma.

***LEPIDOCHELYS KEMPII* (Kemp's Ridley Seaturtle). ATLANTIC NESTING.** Kemp's Ridley nests almost exclusively on beaches of the western Gulf of Mexico, with a center of abundance at Rancho Nuevo, Tamaulipas, Mexico (Márquez 1990. Sea Turtles of the World. An Annotated and Illustrated Catalogue of Sea Turtle Species Known to Date. FAO Species Catalogue, FAO Fisheries Synopsis. 81 pp.). Kemp's Ridley is considered to be the most endangered sea turtle species in the world, although the number of nests has been increasing exponentially in recent years at

FIG. 1. A *Lepidochelys kempii* covering its nest at Sebastian Inlet State Park, Brevard Co., Florida, USA, 02 May 2013.

Rancho Nuevo (National Marine Fisheries Service, U.S. Fish and Wildlife Service; SEMARNAT 2011. BiNational Recovery Plan for the Kemp's Ridley Sea Turtle, *Lepidochelys kempii*, Second Rev. National Marine Fisheries Service. Silver Spring, Maryland 156 pp. + appendices). Most Kemp's Ridleys show synchronous nesting in large groups called *arribadas*. The oldest estimate of the number of nesting females comes from a film made during an *arribada* in 1947, when 40,000 females were believed to have participated in the single event (Hildebrand 1963. Ciencia Méx. 22:105–112). But the population declined drastically through the 1970s (Márquez 1994. Synopsis of Biological Data on the Kemp's Ridley Turtle, *Lepidochelys kempii*. NOAA Tech. Memorandum NMFS-SEFSC-343, 91 pp.; Turtle Expert Working Group 1998. An Assessment of the Kemp's Ridley (*Lepidochelys kempii*) and Loggerhead (*Caretta caretta*) Sea Turtle Populations in the Western North Atlantic. NOAA Tech. Memorandum NMFS-SEFSC-409, 96 pp.). The reason for the decline was suspected to be egg harvesting, killing of nesting females, and drowning of turtles in trawl fisheries in the Gulf of Mexico (Pritchard and Márquez 1973. Kemp's Ridley or the Atlantic Ridley, *Lepidochelys kempi*. I.U.C.N. Monograph. Marine Turtle Series 2. 30 pp.). After addressing these problems—protecting nests, protecting nesting turtles, and implementing turtle excluder devices in commercial trawling (National Research Council 1990, *op. cit.*; Márquez 1994, *op. cit.*; Pritchard 1997. Marine Turt. Newsl. 76:14–17; Turtle Expert Working Group 1998, *op. cit.*), the number of Kemp's Ridleys nesting increased sharply during the period of 1990 to 2010 at both Rancho Nuevo and Padre Island, Texas, the closest U.S. nesting beach to Rancho Nuevo (National Marine Fisheries Service et al. 2011, *op. cit.*).

In addition to *arribadas*, solitary nestings have occurred on beaches in North Carolina, South Carolina, Florida, Alabama, and, more frequently, Texas, USA (Meylan et al. 1990. Herpetol. Rev. 21:19–20; Palmatier 1993. Herpetol. Rev. 24:149–150; Shaver and Caillouet 1998. Mar. Turt. Newsl. 82:1–5; Williams et al. 2006. Marine Turt. Newsl. 113:8; National Marine Fisheries Service et al. 2011, *op. cit.*). In Florida, Kemp's Ridley nests have been confirmed on the beaches along both the Gulf of Mexico and Atlantic Ocean, including the Florida panhandle (Florida Fish and Wildlife Conservation Commission Statewide Nesting Beach Survey program database). The current note documents a Kemp's Ridley that nested twice near the same location on the Atlantic coast of Florida and provides information on nest locations, nest site fidelity, clutch sizes, incubation periods, and nest productivity.

On two occasions in May 2013, visitors to Sebastian Inlet State Park (Brevard Co., Florida) reported a sea turtle nesting in daylight to park rangers. I was contacted by the rangers and located a nesting Kemp's Ridley (Fig. 1). In this first encounter, the turtle was digging an egg chamber at 1045 h Eastern Standard Time on 02 May 2013 at Sebastian Inlet State Park (27.864°N, 80.448°W), on the north side of Sebastian Inlet. When the turtle had stopped depositing eggs (116 eggs), I applied inconel flipper tags to both front flippers and took measurements: standard straight carapace length = 63.8 cm $SCL_{n\text{-}t}$, minimum straight carapace length = 63.4 cm SCL_{min}, maximum straight carapace width = 61.6 cm, curved carapace length notch to tip = 66.5 cm $CCL_{n\text{-}t}$, curved carapace width = 69.8 cm CCW, maximum straight head width = 13.8 cm (Bolton 1999. *In* Eckert et al. [eds.], Research and Management Techniques for the Conservation of Sea Turtles, pp. 110–114. IUCN/SSC Marine Turtle Specialist Group Publication 4). On the day of nesting, winds were at 15–20 knots from the east north-east, seas were choppy, and the sky was overcast. The same Kemp's Ridley nested again at 1040 h Eastern Standard Time on 25 May 2013, 23 days after the first nesting and just 29 m north of the first nest location. The park rangers confirmed the flipper tag numbers applied during the first encounter. The eggs were not counted for the second nesting. Weather conditions were similar to the day of the turtle's first nesting event—windy with rough seas. The location of each nest was marked with a stake placed on the west side of the dune. The first nest was depredated by raccoon(s) prior to hatchling emergence, on the night of 25 June 2013, the 54th day after egg deposition. Sixty-seven live hatchlings were collected from the nest on the morning of 26 June 2013 by a Sebastian Inlet state park ranger. Sixty-three hatchlings survived and were released offshore (27.8817°N, 80.3750°W), about 7.5 km east of Sebastian Inlet. At least 67 of the 116 eggs in the clutch hatched.

The second nest was caged with a self-releasing screen by park rangers. The hatchlings emerged on the night of 15 July 2013 after 52 days of incubation, but many were depredated outside the cage by raccoons, including 59 dead and 1 live (with a damaged eye), collected by a ranger on the morning of 16 July 2013. All the collected hatchlings had damage to the anterior parts of their bodies, including the neck, head, throat, and eyes. On 19 July 2013, I conducted a nest productivity assessment for the second nest. The nest contained five eggs that died during the early incubation (no obvious embryo), nine eggs that died during late incubation (well-developed embryos), four dead hatchlings (completely out of the egg shells), and 108 empty egg shells (this includes four egg shells from dead hatchlings); therefore, the estimated clutch size of the second nest was 122. Hatching success and emergence success of the nest were 88.5% and 85.2%, respectively. I examined the hatchlings that were killed by raccoons for the number of costal (N = 59) and inframarginal (N = 59) scutes, and for the configuration of prefrontal head scales (N = 21, 38 excluded due to head injuries). A typical Kemp's Ridley would have five pairs of costal scutes, four pairs of inframarginal plastron scutes, and two pairs of prefrontal scales, of roughly similar size and shape, with no extra scute between the first and second pair (Pritchard and Mortimer 1999. *In* Eckert et al. [eds.], Research and Management Techniques for the Conservation of Sea Turtles, pp. 21–38. IUCN/SSC Marine Turtle Specialist

Group Publication 4). Fifty-three of 59 (90 %) had five costals on each side, all 59 had four inframarginal plastron scutes, and all 21 showed typical Kemp's Ridley head scute patterns. Given this evidence, I conclude that there is a low probability that the turtles were hybrids.

The size of the nesting turtle, the nest incubation periods, and the weather conditions under which the turtle nested were all similar to descriptions of Kemp's Ridleys nesting at Rancho Nuevo, Mexico (Hildebrand 1963, *op. cit.*; Pritchard and Márquez 1973, *op. cit.*; Márquez 1990, *op. cit.*). The close proximity of the two nest sites (29 m) was similar to observations made on the beach in Sarasota, Florida, where a Kemp's Ridley deposited two nests 274 m apart (Foote and Mueller 2000. *In* Mosier et al. [compilers.], Proceedings of the Twentieth Annual Symposium on Sea Turtle Biology and Conservation. NOAA Tech. Memorandum NMFS-SEFSC-477. 369 pp.). The Kemp's Ridleys in Mexico also nest within a relatively small area of Rancho Nuevo (National Marine Fisheries Service et al. 2011, *op. cit.*).

The hatchlings from these two nests showed no signs of hybridization, based on visual examination of the carapace, plastron, and head scute patterns. This was also the implication of the genetic analysis of Kemp's Ridley hatchlings that emerged in Volusia Co. (Johnson et al. 1999. Florida Sci. 62:194–204). In Mexico, the mating of Kemp's Ridleys is postulated to occur near the nesting beach (Morreale et al. 2007. *In* Plotkin [ed.], Biology and Conservation of Ridley Sea Turtles. The Johns Hopkins University Press, Baltimore, Maryland. 356 pp.; Rostal 2007. *In* Plotkin [ed.], Biology and Conservation of Ridley Sea Turtles. The Johns Hopkins University Press, Baltimore, Maryland. 356 pp.). I do not know where the female described in this account mated. Because Kemp's Ridleys have an alternating gait and leave a track in the sand similar to the nesting emergence of the more commonly observed Loggerhead, the number of their nests might be slightly underestimated in Florida. Eighty Kemp's Ridley nests have been reported from Florida beaches during 1989–2013, with 17 nests reported from the Atlantic coast (Florida Fish and Wildlife Conservation Commission, Statewide Nesting Beach Survey program data). The nesting of Kemp's Ridley in Florida, outside its principal range, may be a function of the recent overall increase in nesting by the species, although the number of Kemp's Ridley nests in Florida during the period of abundant nesting in Mexico (1940s and before) is unknown.

I thank D. Bagley, R. Chabot, A. Finegan, R. Grimaldi, K. Jones, E. Perry, V. Tiseth, and M. Watkins for field support. I also thank J. Boyett, B. Brost, B. Crowder, A. Meylan, and B. Witherington for review of this note.

***MALACLEMYS TERRAPIN* (Diamond-backed Terrapin). ROAD-KILL.** Roads can be a substantial source of mortality for Diamond-backed Terrapins, especially female turtles searching for nesting sites (Woods and Herlands 1997. *In* J. Van Abbema [ed.], Proceedings: Conservation, Restoration, and Management of Tortoises and Turtles—An International Conference, pp. 46–53. New York Turtle and Tortoise Society, New York). Despite the relatively high number of terrapins killed along roadways, few studies have focused on road mortality in this species (Szerlag and McRobert 2006. Appl. Herpetol. 3:27–37). Here, data are presented from a two-year study of terrapin road mortality along a highway in coastal Virginia that has never been systematically surveyed for such mortality.

FIG. 1. Map depicting the location of the road survey transect (red line) along Route 175 in Wallops Island, Virginia. The black hashes demarcate the different sections of the transect, which were separated by bridges in most cases.

We quantified the total number of terrapins killed along a 9-km stretch of Route 175 in Wallops Island, Virginia, USA for two consecutive years (2012, 2013). We monitored the highway between 37.9227°N, 75.4704°W and 37.9372°N, 75.3844°W, which includes a section of causeway that connects mainland Virginia to Chincoteague Island and crosses an area of extensive coastal salt marsh. This causeway is one of the longest stretches of high-traffic, non-viaduct roadway bisecting coastal salt marsh on the Delmarva Peninsula. Surveys were conducted by automobile twice daily at approximately 0800 h and 1700 h from 25 May 2012 to 27 July 2012 and from 29 May 2013 to 30 July 2013. All observed carcasses were collected and removed from the highway after obtaining GPS coordinates.

We observed a total of 89 and 92 dead terrapins for 2012 and 2013, respectively. Road mortality was consistently biased to a particular section of the causeway, located between the Queens Sound and Wire Narrows bridges (Fig. 1, section 5). This section accounted for approximately 32% of total road mortality, but it was around 16% of the total transect length. As expected, of the terrapins whose sex could be determined, the majority were female (95–98%). In 2012, peak mortality rate occurred 26 May with a total of 12 terrapins killed/day, while in 2013 peak mortality occurred approximately two weeks later (8 June), with 10 terrapins killed per day. Cooler water temperatures observed during the spring of 2013 may account for the observed delay in the timing of peak mortality relative to 2012. The last observed road mortality was similar for both years—12 July for both 2012 and 2013; however, a single live terrapin was observed crossing the causeway as late as 15 July 2013.

We found an average annual mortality of 90.5 terrapins killed per 9-km of highway. This is a conservative estimate of the annual rate of mortality at this site, because we did not take detection probability into consideration. In at least five instances over the two-year period we observed terrapin mortality outside of the normal survey times, but all evidence had disappeared by the time we conducted official surveys. In spite of this,

the mortality rate at this site is greater than that reported by Szerlag and McRobert (2006, *op. cit.*), who documented annual mortality to be 53 terrapins for an 8.1-km road (6.5 terrapins/km/yr); however, their study and ours documented substantially less mortality than that reported in a Cape May, New Jersey study. That seven-year survey documented a total mortality of 4020 terrapins with an annual mortality rate of 22.8 terrapins/km/yr (Wood and Herlands 1997, *op. cit.*). Nevertheless, due to the substantial number of terrapins killed along the Route 175 causeway, we recommend the installation of terrapin barriers to reduce road mortality. We also recommend that conservation resources should be prioritized to section five (Fig. 1) of the causeway, the greatest source of mortality.

We thank the Chincoteague Bay Field Station for housing and logistical support, Kutztown University for financial assistance, and the Virginia Department of Game and Inland Fisheries and Virginia Department of Transportation for permitting. E. Wink, L. Piorkowski, and S. Krieg assisted with data collection.

***PODOCNEMIS ERYTHROCEPHALA, PODOCNEMIS EXPANSA, PODOCNEMIS SEXTUBERCULATA, PODOCNEMIS UNIFILIS* (Red-headed Amazon River Turtle, Giant South American River Turtle, Six-tubercled Amazon River Turtle, Yellow-spotted Amazon River Turtle). COEXISTENCE.** Here we report the first record of four species of freshwater turtles of the same genus occurring in the same locality. *Podocnemis expansa* and *P. unifilis* are found in Brazil, Bolivia, Colombia, Ecuador, Guyana, Peru, Suriname, and Venezuela; *P. erythrocephala* can be found in Brazil, Colombia, and Venezuela; *P. sextuberculata* is present in Brazil, Colombia, and Peru (Vogt 2008. Tartarugas da Amazônia. Gráfica Biblos, Lima, Peru. 104 pp.) This note is based on a survey in Amazonas (Brazil), in the Municipality of São Sebastião do Uatumã, Sustainable Development Reserve Uatumã, in Lake Jaraoacá (2.37705555556°S, 58.3048333°W; WGS 84). Between January and August 2012, using trammel nets, we captured 30 specimens of *P. expansa* (238.6 ± 63.9 mm SCL; mean ± standard deviation), 15 of *P. erythrocephala* (212.4 ± 27.5 mm SCL), 14 of *P. sextuberculata* (220.1 ± 11.4 mm SCL), and six specimens of *P. unifilis* (215.7 ± 14.7 mm SCL) distributed among males, females, and juveniles. This is also the first record of *P. sextuberculata* occuring in a black water lake; they usually occur only in white or clear water rivers and lakes.

We are grateful to CPPQA for financial and logistical support and CNPq for scholorship to F.L.R. Cunha. We thank Claudomiro dos Santos Gomes and Adalberto Costa de Almeida for the field assistance and Natali Bordon for reviewing the manuscript. Research conducted under research permit Nº 063/2011 CEUC / SDS.

VOGT**, CBIO Instituto Nacional de Pesquisas da Amazônia (INPA), Av. André Araújo, 2936, Petrópolis, CEP 69.067-375 Manaus, Amazonas, Brazil (e-mail: vogt@inpa.gov.br).

***PODOCNEMIS LEWYANA* (Magdalena River Turtle). MERCURY LEVELS.** *Podocnemis lewyana* is an endangered species endemic to northern Colombia, where it suffers from habitat degradation and over-exploitation for its meat and eggs (Páez et al. 2009. Chelon. Res. Monogr. 5:024.1–024.6). Northern Colombia is a globally significant focus for mercury contamination due to its widespread use there in artisanal gold mining activities (United Nations Environment Programme 2002. Global Mercury Assessment. Geneva, Switzerland).

Between January and March of 2012, we obtained samples from eight adult female *P. lewyana* from subsistence fishermen at the time the turtles were sacrificed in Puerto Berrío, Antioquia (6.4942°N, 74.3882°W, WGS84; elev. 105 m). They ranged in size from 28.3 to 45.6 cm straight-line carapace length (mean = 39.3 cm). Samples of blood, muscle, and carapace tissue were held on ice until transported to the laboratory, where they were digested with H_2SO_4, HNO_3, and $KMNO_4$. Total mercury content was then determined by flameless atomic absorption spectrometry, using a Buck Scientific 410 Cold vapor Mercury Analyzer (Buck Scientific, Inc, Norwalk, Connecticut). The mercury concentration averaged 0.79 ± 1.04 ug/g wet weight (mean ± SD) for muscle, 0.69 ± 1.06 ug/g for carapace and 0.13 ± 0.18 ug/g for blood. Thus, humans who consume *P. lewyana* meat run a health risk, since this tissue exhibited mercury concentrations above the maximum level (0.5 ug/g Hg) recommended by the World Health Organization (WHO 2000. Guidance for Assessing Chemical Contaminant Data for Use in Fish Advisories. Vol. 2. Risk Assessment and Fish. WHO, Washington, D.C.).

Mercury biomagnifies as it moves up the food chain, but despite being herbivorous, these *P. lewyana* individuals exhibited higher levels of mercury bioaccumulation in their tissues than those documented for the omnivorous Colombian Slider (*Trachemys callirostris*) in this same drainage (Zapata et al. 2014. Bull. Environ. Contam. Toxicol., *in press*. DOI: 10.1007/s00128-014-1198-5). Perhaps the higher levels were related to the larger size of the *P. lewyana* individuals that were sampled, which presumably were older and therefore had experienced longer exposure times to this contaminant than the average adult slider turtle.

We thank the Comité para el Desarrollo de la Investigación (CODI) and the Programa de Sostenibilidad 2010–2012 of the Universidad de Antioquia for funding this study.

***PODOCNEMIS SEXTUBERCULATA* (Six-tubercled Amazon River Turtle). MORPHOLOGY, EXTRA LIMB.** On 18 October 2013 a female *Podocnemis sextuberculata* laid 18 eggs in a nest on Praia do Farias (Municipality of Oriximiná. Reserva Biológica do Rio Trombetas: Para, Brazil; 1.25°S, 56.833333°W, WGS84). This beach is used annually for nesting by *Podocnemis* (*P. expansa*, *P. unifilis*, and *P. sextuberculata*), from August–December. Eleven of these eggs hatched on 7 December. Mean nest temperature was 32.5°C (temperature recorded hourly by an Onset Tidbit Data Logger placed in the nest). One of the hatchlings had five limbs, two anterior and three posterior. The four in the expected locations were normal, the fifth appendage had its origin at the medial juxtaposition of the femoral and anal scutes; the atrophied appendage has normal skin, scale, and toe morphology, but is about 50% smaller than the other two hind limbs (Figs. 1, 2). The plastron and carapace are disrupted at the insertion point of the extra limb. The turtle was able to walk and swim

FIG. 1. Posterior carapacial view of hatchling *Podocnemis sextuberculata* with supernumerary hind limb.

FIG. 2. Posterior plastral view of hatchling *Podocnemis sextuberculata* with supernumerary hind limb.

without any difficulties. The added appendage is capable of moving up, covering the cloaca with the foot, or down. It is able to spread the toes normally. Usually the appendage is held tight against the plastron with the ventral aspect of the foot covering the cloaca. To our knowledge this is the first report of a pleurodiran turtle with five appendages. A *Chrysemys picta* without hind legs, which died while hatching, has been reported (Ewert 1979. *In* M. Harless and H. Morlock [eds.], Turtles: Perspectives and Research, pp. 333–413. John Wiley and Sons, New York). Hildebrand (1938. J. Hered. 29:243–254) reported a *Malaclemys terrapin* with a rudimentary fifth leg. The turtle described here remains alive at Projeto Tartarugas da Amazônia in Manaus.

Financial and logistical support for the study were provided by Projeto Tartarugas da Amazônia and REBIO Trombetas (ICMBio), CNPq provided a scholorship for F. F. Pereira. Joselino and Maneco are thanked for field assistance. This research was authorized by permit No40084-3/2013 ICMBio.

***RHINOCLEMMYS RUBIDA PERIXANTHA* (Colima Wood Turtle). DIET.** *Rhinoclemmys rubida perixantha* is a relatively small terrestrial turtle, native to the tropical deciduous forests of western Mexico, ranging from the states of Michoacán to Jalisco (van Dijk et al. 2007. *In* IUCN 2013. IUCN Red List of Threatened Species. Ver. 2013.1 http://www.iucnredlist.org. Accessed 05 September 2013). Little information exists on the diet of *R. r. perixantha*, however observations of fecal samples from this species on the Chamela-Cuixmala Biosphere Reserve in 2011 indicate the diet of this population consists of cactus (*Opuntia* spp.), isopods, and the seed pits of fleshy fruit (Holcomb 2012. The Tortoise. [The Turtle Conservancy]. 1:57). The closely related *R. r. rubida* is known to feed on cactus (*Opuntia* spp.), fruit, and small arthropods at the Behler Chelonian Center (Liu 2012. The Tortoise. [The Turtle Conservancy]. 1:59). Here we present additional observations on the diet of *R. r. perixantha*.

On four separate occasions in the lowland tropical deciduous forest of the Chamela-Cuixmala Biosphere Reserve (19.49868°N, 105.04449°W) in Jalisco, Mexico, we observed a large quantity of *Guapira macrocarpa* seeds and flesh in the feces of *R. r. perixantha*. The first observation was on 1 July (adult male), followed by three more observations on 3 July (adult male), 19 July (adult female), and 21 July (juvenile), 2012. On three occasions *R. r. perixantha* was observed actively feeding on the fallen fruits of *Guapira macrocarpa* (1, 3, and 21 July; Fig. 1). Upon discovery, specimens were temporarily collected for measurement and collection of fecal samples. In addition to *G. macrocarpa* seeds, fecal samples revealed cactus fiber, and small amounts of unidentified seeds. This appears to be the first record of foraging and identified food sources for *R. r. perixantha*.

Guapira macrocarpa is among the most abundant tree species on the Chamela-Cuixmala Biosphere Reserve and bears fruit during the onset of the four-month rainy season, typically in July (Durán et al. 2002. *In* Noguera et al. [eds.], Historia Natural de Chamela, pp. 443–472. Universidad Nacional Autónoma de México). During this period the fruit from *G. macrocarpa* is known to be an important food source for *Trogon citreolus* (Citreoline Trogon; Renton and Vega 2002. *In* Noguera et al. [eds.], Historia Natural de Chamela, pp. 345–346. Universidad Nacional Autónoma de México) and *Glossophaga soricina* (Pallas's Long-tongued Bat; Stoner 2002. *In* Noguera et al. [eds.], Historia Natural de Chamela, pp. 379–395. Universidad Nacional

FIG. 1. *Rhinoclemmys rubida perixantha* on the Chamela-Cuixmala Biosphere Reserve shortly after eating the red fleshy fruit of *Guapira macrocarpa*.

Autónoma de México). Observations of *R. r. perixantha* foraging on this fruit in the wild and its identification in fecal samples suggest *G. macrocarpa* may also be an important food source for this turtle during the rainy season. In addition, *R. r. perixantha* may potentially be an important seed dispersing agent for *G. macrocarpa*.

I thank Daniel Beck for logistical and moral support for my endeavors in the tropical deciduous forest, Caleb Loughran for reviewing all versions of this note, and Kerry Holcomb for inspiring my interest in these turtles.

***TERRAPENE CAROLINA CAROLINA* (Eastern Box Turtle). POTENTIAL MODE OF DISPERSAL IN TERRESTRIAL GASTROPODS.** *Terrapene carolina carolina* has been shown to aid in the dispersal of both fungal spores (Jones et al. 2007. Am. Midl. Nat. 157:121–126) and seeds (Braun and Brooks 1987. Am. Midl. Nat. 117:312–318). Both of these instances were accomplished through ingestion and defecation and are something that would be expected based on *T. c. carolina* feeding habits (Dodd 2001. North American Box Turtles: a Natural History. Univ. Oklahoma Press, Norman. 231 pp.). This report describes the dispersal of an additional organism (e.g., terrestrial gastropod) through attachment to the carapace of *T. c. carolina*. Box turtles tend to have varying home range sizes depending on the individual, but generally stay within a small region (Dodd 2001, *op. cit.*), therefore, long distance dispersal by invertebrates via attachment to the carapace is not likely. However, there is potential for dispersal into localized areas where previous colonization has not occurred. There is also an opportunity for re-colonization of areas that have experienced some type of catastrophic disturbance.

On 8 June 2011 while conducting field work at Lilley Cornett Woods Appalachian Ecological Research Station, Letcher Co., Kentucky, USA (37.07692°N, 82.99578°W; NAD 83), I observed a small terrestrial gastropod (*Punctum minutissimum*) that had attached itself to the carapace of a *T. c. carolina*. Although it is unknown whether the terrestrial gastropod intentionally attached itself to the carapace, this represents a potential mode of dispersal in these organisms, even if unintentional. This observation demonstrates a mode through which microsnails (i.e., those that are < 5 mm in diameter), as noted here, may potentially colonize or re-colonize local areas. These organisms have extremely limited mobility and are confined to small home ranges throughout their lives (Baur and Baur 1988. Veliger 30:372–376), thus making them susceptible to localized extinctions during catastrophic events. This may also represent a manner by which terrestrial gastropods could navigate through areas that would generally present a barrier for dispersal, such as shallow water. Though terrestrial gastropods are often consumed by *T. c. carolina* (Dodd 2001, *op. cit.*), this observation demonstrates an instance in which a prey organism could potentially derive benefit from the presence of a potential predator. To my knowledge, this is the first such observation of this phenomenon in this area.

DANIEL A. DOUGLAS, Department of Biological Sciences, Eastern Kentucky University, Richmond, Kentucky 40475, USA; e-mail: dnl.douglas83@gmail.com.

***TRACHEMYS SCRIPTA ELEGANS* (Red-Eared Slider). MOVEMENT.** Freshwater turtles are capable of long distance movements; such movements may be associated with reproduction, periods of dormancy, and searches of suitable habitat (i.e., ephemeral wetlands; Ernst and Lovich 2009. Turtles of the United States and Canada, 2nd ed., Johns Hopkins Univ. Press, Baltimore, Maryland. 827 pp.).

At ~ 0900 h on 18 July 2012, a female *Trachemys scripta elegans* (carapace length = 195 mm, mass = 1025 g) was captured in a hoop trap on the North Oconee River in Clarke Co., Athens, Georgia, USA, and released at the point of capture. This individual was recaptured at ~ 1100 h on 22 July 2012 in another hoop trap 1.65 km downstream from where it was first captured. Distance of movement was determined using GPS and Google Earth Pro. At the time of trapping, the stream was at base flow (30 cubic feet/sec), with numerous riffle areas, which constricted aquatic movement downstream.

Although long distance movement in turtles is not unusual, our observation might be of interest because this turtle apparently followed the watercourse for a considerable distance at a time when movement was difficult. In addition, females are often considered more sedentary than males (Parker 1984. Am. Midl. Nat. 112:280–293). In Carolina Bays of South Carolina, significantly more males were captured than females of those turtles making overland movements (Morrealle et al. 1984. Can. J. Zool. 62:1038–1042). Additionally, the longest movements were made exclusively by males, supporting a hypothesis that differing reproductive tactics might explain the differences in seasonal activity of males and females. It is possible that the movement we observed might have been associated with disturbance from handling, although this was minimized in the field.

***TRACHEMYS SCRIPTA* (Red-Eared Slider), *PSEUDEMYS TEXANA* (Texas River Cooter), *CHELYDRA SERPENTINA* (Snapping Turtle). FEEDING BEHAVIOR AND SCAVENGING.** On 25 March 2013 we observed a *Pseudemys texana* consuming algae from the carapace of a *Trachemys scripta* in the Turtle Pond at The University of Texas at Austin. The Turtle Pond contains an urban population of *T. scripta*, *P. texana*, at least two individuals of *Chelydra serpentina*, and a lone individual of *Apalone spinifera* (presumed to be introduced). Algae covers the carapaces of many turtles in the pond; some individuals are entirely covered in algae while others lack it. This is the first time that the consumption of algae from a turtle shell has been documented between these two species; it remains unknown if this represents an opportunistic feeding event or if there is a more substantial symbiotic relationship between these species. Symbiotic cleaning behavior has been noted previously in a single pond in Ontario, Canada, in which several individuals of *Chrysemys picta* were observed eating algae and leeches off of the shell and skin of several *Chelydra serpentina* (Krawchuk et al. 1997. Can. Field Nat. 111:315–317). Individual *Chelydra* in the pond with parasites removed by *Chrysemys* had significantly fewer leeches than *Chelydra* elsewhere, but the effects of algae-removing behavior by the turtles was not mentioned in this regard. Although *Chelydra* is found in the Turtle Pond, no individuals have been observed participating in algae removal. The observed interaction between *P. texana* and *T. scripta* was

captured on video and is available for review (http://dx.doi.org/10.6084/m9.figshare.787749).

On 8 April 2013 we observed multiple adult *T. scripta* cannibalistically scavenging a decapitated adult conspecific in the Turtle Pond. These individuals bit at the exposed flesh between the forelimb and the plastron-carapace bridge, pulling with the head and neck and pushing with the forelimbs to tear off chunks before consuming the flesh. A video was captured of the behavior and is available for review (http://dx.doi.org/10.6084/m9.figshare.787748). This behavior is probably not truly cannibalistic, but rather represents opportunist cannibalistic scavenging. Mitchell (1986. SSAR Herpetol. Circ. No. 15, 37 pp.), in a review of cannibalistic events for turtles, reported eight incidents, seven of which involved adults consuming juveniles; the eighth incident did not report information about the age of participants.

Also on 8 April 2013, we observed an individual of *T. scripta* consuming a juvenile of *Chelydra serpentina* in the Turtle Pond. When the observation was made, the juvenile was already deceased and partially consumed. The feeding behavior was similar to the cannibalistic scavenging described previously. The juvenile *Chelydra* was held in the mouth of the adult *Trachemys*, which pushed with its forelimbs and pulled with its neck to try to destroy the weakly ossified shell and consume the juvenile. This behavior was captured on video, which is available for review (http://dx.doi.org/10.6084/m9.figshare.810515).

CROCODYLIA – CROCODILIANS

***CROCODYLUS MORELETII* (Morelet's Crocodile). DIET.** Crocodylus moreletii inhabits freshwater wetlands throughout much of the Atlantic lowlands of Mexico, Guatemala, and Belize (Groombridge 1987. In Webb et al. [eds.], Wildlife Management: Crocodiles and Alligators, pp. 9–21. Surrey Beatty & Sons, Pty. Ltd, Sydney). On 18 April 2013 at 2230 h, while conducting a crocodile spotlight survey along the Río Hondo (17.9°N, 88.86°W, datum WGS84; 5 m elev.) on the border between Mexico and Belize, we found a yearling Morelet's Crocodile (32 cm total length, 130 g) that had just captured an adult male Mexican Greater Funnel-eared Bat (*Natalus mexicanus*) near shore. The young crocodile continued holding the bat between its jaws after we captured it (Fig. 1). Crocodilians are mainly nocturnal hunters, so field observations on actual prey species taken are scarce. However, *Crocodylus porosus* and *C. johnstoni* catch flying foxes and other bats in some regions of Australia (Pooley 1989. *In* Ross [ed.], Crocodiles and Alligators, pp. 76–91. Facts On File, Inc., New York). To our knowledge, this is the first documented case of bats being part of the diet of *C. moreletii*. Previous dietary studies reported aquatic and terrestrial insects, arachnids, aquatic gastropods, crustaceans, fish, amphibians, reptiles, birds, and terrestrial mammals, but bats were not included among the prey items recovered from stomach contents (Platt et al. 2006. Herpetol. J. 16:281–290). More interesting is the fact that very small crocodiles such as this one are known to consume mostly

invertebrates and small fish rather than birds or mammals (Platt et al. 2002. Herpetol. J. 12:81–84). During spotlight surveys to study crocodile populations we commonly observe bats flying above the water (Fig. 2), and this crocodile likely caught the bat when it came low to drink.

We thank Irving A. Rosas-López and Roberto Herrera-Pavón for field assistance, and Enrique Escobedo Cabrera for identifying the bat species and determining its age class. Special thanks to Steven G. Platt for comments on the manuscript.

SQUAMATA — LIZARDS

***AMBLYRHYNCHUS CRISTATUS* (Marine Iguana). POLYDACTYLY.** Polydactyly is relatively uncommon in lizards and certainly occurs in wild lizard populations at a frequency near or lower than 1/1000 (II, pers. obs. on Pacific islands of > 10,000 lizards). Thus, each observation is valuable and should be reported. Among reptiles, polydactyly has been reported within chelonians and several lizard families (chamaeleonids, tropidurids,

FIG. 1. Left (on the left) and right (on the right) hands ventral views of *Amblyrhynchus cristatus* (MNHN 1903.0007) showing the supernumerary finger I on both sides of the animal. Note that a mite is present on left side between fingers I and II.

FIG. 2. Left (on the left) and right (on the right) hands dorsal views of *Amblyrhynchus cristatus* (MNHN 1903.0007) showing the supernumerary finger I on both sides of the animal.

lacertids, and gekkonids). Most recent reports concern lizards from distinct families and geographical origin (e.g., Carretero et al. 1995. Bol. Assoc. Herpetol. Esp. 1995:11–13; Megía 2012. Bol. Asoc. Herpetol. Esp. 23:54–56). One report among the Rhynchocephalia has been omitted in all previous papers reporting cases of polydactyly (e.g., Bauer et al. 2009. Herpetol. Notes 2:243–246). This important statement was published in a local herpetological association journal (Anonymous 2007. Society for the Research on Amphibians and Reptiles in New Zealand 33:12). That case of symmetrical polydactyly reported the occurrence of six toes on both front feet in a hatchling *Sphenodon punctatus*. Ineich (p. 228; 1987. Recherches sur le peuplement et l'évolution des reptiles terrestres de Polynésie française. Ph.D. Thesis, USTL Montpellier, France. 511 pp.) also reported the first cases of polydactyly in a skink (*Cryptoblepharus poecilopleurus*; Easter Island) and the first in a gecko (*Gehyra oceanica*; French Polynesia), both also omitted in following reports. Paris Natural History Museum (MNHN) possesses two specimens of *Amblyrhynchus cristatus* (MNHN 1903.0007–8) that were collected together at Gardner Island on the Galapagos Archipelago in the early twentieth century (note, however, that there are two Galapagos Islands named after Lord Gardner, one near Charles Island and another near Hood Island; Slevin 1959. The Galapagos Islands, A History of Their Exploration. Proc. California Acad. Sci. 25:i–x + 1–150). Both female MNHN specimens were donated by Mr. Rosenberg (and perhaps collected by him) on 31 January 1903 to the MNHN collections. Among those specimens, one (MNHN 1903.0007) exhibits polydactyly on both hands, whereas the other has normal fingers and toes. The adult specimen with supernumerary fingers displays six fingers on both hands (SVL = 192 mm, tail length = 305 mm, total length = 497 mm). The aberrant specimen is unique in two ways: First, polydactyly in this specimen is symmetrical and identical on both sides (Figs. 1, 2); secondly, the supernumerary finger is certainly placed before what should normally be finger I. Our specimen was, however, not x-rayed, and consequently, osteological basis for its polydactyly condition cannot be discussed further here. Lazi et al. (2012. Herpetol. Notes 5:277–279) related a case of true polydactyly or brachydactyly in a *Podarcis muralis* (Lacertidae) from Serbia showing six toes on each foot. Their observation concerned hindlimbs contrary to the Marine Iguana reported here, but was symmetrical as in the present case. Our report is the first regarding polydactyly in the Iguanidae. Our observations and all the previous ones together seem to argue that such malformations are not related to phylogenetic or geographic origin of an individual. Note, however, that they seem to have a strong association with islands (e.g., French Polynesia, Easter Island, Palmyra Atoll, New Zealand) and this could be perhaps an artifact linked to low island predation levels allowing individuals with such malformations to grow to adult stage and thus increasing their chance to be sampled.

IVAN INEICH, Muséum national d'Histoire naturelle, Département de Systématique et Evolution, CNRS-UMR 7205 (Origine, Structure et Evolution de la Biodiversité), Reptiles CP 30, 57 rue Cuvier, F-75005 Paris, France (e-mail: ineich@mnhn.fr); **AURELIEN MIRALLES**, CNRS-UMR5175 CEFE, Centre d'Ecologie Fonctionnelle et Evolutive, 1919 route de Mende, 34293 Montpellier cedex 5, France.

***ANOLIS CRISTATELLUS WILEYAE* (Virgin Islands Crested Anole). NOCTURNAL ACTIVITY.** The highly speciose genus *Anolis* is widespread in the New World tropics, with the Caribbean a major center of radiation (e.g., Schwartz and Henderson 1991. Amphibians and Reptiles of the West Indies: Descriptions, Distributions, and Natural History. Univ. Florida Press, Gainesville, Florida. 720 pp.; Roughgarden 1995. Anolis Lizards of the Caribbean: Ecology, Evolution, and Plate Tectonics. Oxford University Press, New York. 200 pp.; Losos 2009. Lizards in an Evolutionary Tree: Ecology and Adaptive Radiation of Anoles. Univ. California Press, Berkeley. 528 pp.). Several *Anolis* spp. have been described as human commensals in that they have colonized and proliferated in anthropogenic habitats such as urban gardens, plantations, and orchards (e.g., endemic *A. trinitatus* and exotic *A. sagrei* on St. Vincent, Windward Islands, Lesser Antilles; Treglia 2006. Iguana 13:252–263; exotic *A. sagrei* on Taiwan; Norval et al. 2002. Zool. Stud. 41:332–336). All species are typically diurnal. This note documents an instance of nocturnal activity in *A. cristatellus wileyae*, which has a widespread distribution in the Virgin Islands, and is known to occur in anthropogenic habitats (MacLean 1982. Reptiles and Amphibians of the Virgin Islands. Macmillan Education Limited, London and Basingstoke, UK. vii + 52 pp.).

Observations occurred in a small ground floor hotel bedroom at Nanny Cay Resort and Marina, on the coast at the east end of Tortola Island, British Virgin Islands (18.400833°N, 64.56888°W, datum WGS84; elev. ~5 m), during a stay by the second author (JEM). On 2 April 2013, 1939 h, JEM entered the unilluminated room, switched on the overhead ceiling light, and observed a small adult (estimated SVL ~50 mm) female *A. c. wileyae* stationary in resting stance with eyes open near the top of the shade of an unilluminated electric lamp, situated ~0.2 m from the bed on a bedside table. The subject was photographed with a digital camera (Fig. 1) but was apparently undisturbed by the flash and the presence of the observer, and remained in the same position on the lamp shade for a further ~7 minutes; it eventually leaped down to the side table, then to the floor, and was lost to

PHOTO BY J. E. METCALFE

FIG. 1. Female *Anolis cristatellus wileyae* on lamp shade in a hotel room, Tortola Island.

view. JEM had been coming and going from the room previously during the day, but had not observed the subject, and had last left the room ~1¼ h previous to observations just after sunset (1832 h on 2 April 2013, Tortola Is.) when the overhead light was switched off and the curtains were closed, leaving the room in darkness. While very low illumination in the room through the window and gaps in the curtains might have been available in the gloaming from outside shortly after we left the room, later perhaps from exterior lights, or under the door from hallway lights, at some point during the intervening ~1¼ h period the lizard had climbed the furniture and the lamp shade, in darkness or near-darkness, as typical of arboreal perching behavior at dusk reported in many *Anolis* spp. (e.g., *A. uniformis* in Mexico; Cabrera-Guzman and Reynoso 2010. Rev. Mex. Biodivers. 81:921–924; *A. grahami*, *A. lineatopus*, and *A. valencienni* in Jamaica; Singhal et al. 2007. Behaviour 144:1033–1052; general discussion, Losos 2009, *op. cit.*), and the lamp shade in the above case was probably the highest accessible point in the room. The subject reported herein was the only *A. c. wileyae* observed on Tortola Island during the brief stay by JEM.

This observation is apparently the first report of nocturnal activity in typically diurnal *Anolis c. wileyae* within a human-occupied building on Tortola Island. Some congenerics (e.g., *A. equestris*) may remain active for a brief period after nightfall via thigmothermy on warm substrates. An alternative explanation is that availability of light rather than heat is the factor limiting activity in *Anolis* spp., if sufficient illumination is provided by incandescent or fluorescent lights, where insects attracted to artificial lights may provide an attraction for opportunistic foraging anoles, as noted in several reviews (e.g., Henderson and Powell 2001. Carib. J. Sci. 37:41–54; Perry and Fisher 2006. *In* Rich and Longcore [eds.], Ecological Consequences of Artificial Night Lighting, pp. 169–191. Island Press, Washington, DC), the most recent and extensive of which reported 17 *Anolis* spp. as engaged in this behavior (Perry et al. 2008. *In* Mitchell et al. [eds.], Urban Herpetology, pp. 239–256. Herpetol. Conserv. Vol. 3. SSAR, Salt Lake City, Utah), and there have been several subsequent reports (e.g., Stroud and Giery 2013. Herpetol. Rev. 44[4]:660–661); these reports indicate nocturnal foraging around artificial lights might be widespread in *Anolis* spp. Nocturnal foraging activity at artificial lights was reported for the nominate race *A. c. cristatellus* in Puerto Rico (Garber 1978. Trans. Kansas Acad. Sci. 81[1]:79–80) and as exotics in the Dominican Republic, Hispaniola (Schwartz and Henderson 1999, *op. cit.*), and for *A. c. wileyae* which were in turn predated by the typically diurnal snake *Liophis portoricensis anegadae* on Guana Island, British Virgin Islands (Perry and Lazell 2000. Herpetol. Rev. 31[4]:227; Perry and Powell 2009. IRCF Reptiles & Amphibians 16[1]:6–17, photograph p. 11:B). The above case of a wild *A. c. wileyae* active in the dark in order to attain a sleeping perch demonstrated that this species will also engage in nocturnal activity other than foraging under artificial lights.

DEAN C. METCALFE, PO Box 4046, Werrington, NSW, Australia 2747 (e-mail: dean_metcalfe@yahoo.com.au); **JENNIFER E. METCALFE**, PO Box 734, South Brisbane, Queensland, Australia, 4101 (e-mail: jenni@econnect.com.au).

***ANOLIS SAGREI* (Brown Anole). PREY STEALING BEHAVIOR.** *Anolis sagrei* is native to Cuba and the Bahamas, and has been introduced throughout many tropical and subtropical regions of the world (Kolbe et al. 2004. Nature 431:177–181). Trunk-ground anole ecomorphs (e.g., *A. sagrei*) utilize a sit-and-wait foraging strategy where they detect prey visually by their movement (Losos 2009. Lizards in an Evolutionary Tree: Ecology and Adaptive Radiation of Anoles. Univ. of California Press, Berkeley. 528 pp.). The diet of *A. sagrei* consists primarily of invertebrates, but adults occasionally eat other lizards including young of their own species (Cochran 1989. Herpetol. Rev. 20:70; Gerber and Echternacht 2000. Oecologia 124:599–607).

On 13 October 2013, we observed an adult *A. sagrei* steal a subdued spider from a spider-wasp (Hymenoptera: Pompilidae) on a spoil island located at Tomoka State Park, Ormond Beach, Florida, USA (29.349599°N, 81.090158°W; WGS 84). Spider-wasps paralyze and then lay eggs inside spiders, which subsequently hatch inside the spider host where the larvae feed (Eaton and Kaufman 2007. Kaufman Field Guide to Insects of North America. Houghton Mifflin, New York. 392 pp.).

The wasp attacked a funnel-web spider (Araneae: Agelenidae), which was located on the ground at the base of a small tree. The spider attempted to flee about 0.5 m before becoming motionless, presumably due to venom injected by the wasp. The wasp quickly grabbed the spider and began to drag it backwards towards the site of the initial confrontation. An adult *A. sagrei* had been observing the wasp/spider interaction from about 0.5 m above in the small tree. As the wasp was dragging the spider, the *A. sagrei* jumped to the ground, bit and stole the spider, and quickly returned to its perch where it began to consume the spider. The wasp took flight when the *A. sagrei* bit the spider and fled the area within a few minutes following the event.

Anolis sagrei are important components of tropical and subtropical communities that affect invertebrate populations directly (i.e., depredation) and indirectly (i.e., competition) (Spiller and Schoener 1990. Oecologia 83:150–161; Huang et al. 2008. Ecol. Entomol. 33:569–576). While it is known that *A. sagrei* depredate spiders opportunistically (Spiller and Schoener 2001. Ecology 82:1560–1570), there are no studies to our knowledge that have documented direct competition between spider-wasps and anoles for spider prey. The frequency of these interactions depends upon numerous factors (e.g., wasp density, lizard density) and might contribute to shaping community structure where anoles and spider-wasps occur sympatrically, both in and outside the native range of *A. sagrei*.

WARNER**, Department of Biology, University of Alabama at Birmingham, Birmingham, Alabama 35294, USA.

***ASPIDOSCELIS TIGRIS AETHIOPS* (Sonora-Sinaloa Desert Whiptail). SIZE AND REPRODUCTION.** I assessed SVL and reproductive characteristics for *Aspidoscelis tigris* based on a sample from among the southernmost continental areas known for the species, populations which occur in a coastal state of western México. Use of the trinomial *A. t. aethiops* for these populations of diminutive lizards (max. SVL 67 mm) is problematic. Further studies may show that they represent an undescribed subspecies (Walker, unpubl. data). I examined 28 specimens from the California Academy of Sciences (CAS 115648–115675) collected by A. E. Greer and F. W. Burley on 20 July 1963 from ~7 km NE of Topolobampo near the road to Los Mochis (25.69°N, 109.04°W; datum NAD27) in the northern part of Sinaloa State, México. This site is beyond the southern limits of the Sonoran Desert as mapped by Brown and Wright (1994. Herpetology of the North American Deserts. Proc. Symp. Southwest. Herpetol. Soc. Spec. Publ. 5. Van Nuys, California. XX pp.). Data for SVL and clutch size based on dissection of the CAS sample are presented by ranges of variation, sex as a ratio, and/or means (to one decimal place) ± 1 SE.

Numbers of males and females of *A. t. aethiops*, respectively (in parens), by size (as 5 mm increments in SVL where applicable) among the 28 specimens were: 50–54 (2:4), 55–59 (3:0), 60–64 (10:6), 65–67 (3:0), and overall sex ratio from opportunistic collecting (18:10). Among the 10 females in the sample, nine were sexually mature (i.e., >51 mm SVL), seven were gravid, five had yolked ovarian follicles, and two had oviductal eggs. Sexual dimorphism in SVL for the Sinaloa population of *A. t. aethiops* is not apparent at $P = 0.05$, based on data for adult males (60.7 ± 0.91, 53-67, N = 18) compared with adult females (58.7 ± 1.47, 52–63, N = 9). Among females 50–54 mm SVL, 2 (50%) were gravid; clutch size was 1–2 (mean = 1.5). Among females 60-64 mm SVL, five (83.3%) were gravid; clutch size was 1–2 (mean = 1.8). For the single-date Sinaloa sample, two females had clutches of one egg and five females had clutches of two eggs. Clutch size for seven females was 1.7 ± 0.18; there is no relationship between clutch size and SVL for the seven Sinaloa females of *A. t. aethiops* (based on adjusted $r^2 = -0.18$).

The sample of *A. t. aethiops* from the area northeast of Topolobampo, Sinaloa, referenced herein is ~331 km straight line distance southsoutheast of the nearest continental site at Estación Ortiz (28.289972°N, 110.716889°W; datum WGS84), Sonora, from which specimens were previously used to assess SVL and reproductive characteristics at that latitude in this species (Walker et al. 2005. Herpetol. Rev. 36:316–317). The present study revealed a geographic trend from significantly higher means for adult male SVL (71.7 ± 0.71, range 6087, N = 91), adult female SVL (68.5 ± 0.73, 6081, N = 60), and clutch size (2.2 ± 0.09, range 14, N = 43) at Estación Ortiz compared with the aforementioned lower means for the sample from northeast of Topolobampo, Sinaloa.

I thank Robert C. Drewes and Jens V. Vindum, California Academy of Sciences, for the opportunity to examine specimens in their care.

JAMES M. WALKER, Department of Biological Sciences, University of Arkansas, Fayetteville, Arkansas 72701, USA; e-mail: jmwalker@uark.edu.

***ASPIDOSCELIS TIGRIS PUNCTILINEALIS* (Sonoran Tiger Whiptail). UPLAND HABITATS.** The geographical distribution of *Aspidoscelis tigris punctilinealis* (= *Cnemidophorus tigris gracilis*; see Reeder et al. 2002. Amer. Mus. Novitat. 3365:161; Taylor and Walker 1996. Copeia 1996:140–148; Walker et al. 1966. Copeia 1966:498505) includes Isla Tiburón (type locality), Gulf of California, Sonora, Mexico, and large mainland areas in Sonora and Arizona (see map in Dessauer et al. 2000. Bull. Amer. Mus. Nat. Hist. 246:1148; Taylor and Walker 1996, *op. cit.*; Walker et al., *op. cit.*). In this report we show that the popular conception of *A. t. punctilinealis* (Sonoran Tiger Whiptail) in Arizona as the ubiquitous, moderately large (~95 mm maximum SVL), wary, and rapidly-moving denizen of openstructured Sonoran desertscrub consisting of relatively stable creosote and/or mesquite flats (Dessauer et al., *op. cit.*; Taylor and Walker 1996, *op. cit.*) is inadequate to explain the existence of much larger lizards (>105 mm maximum SVL) in topographically complex upper elevation disturbed ecotones connecting woodland biomes in the central part of the state. Herein, we describe atypical habitats utilized by lizards that apparently represent *A. t. punctilinealis* (based on dorsal and ventral color patterns) at the northern terminus of the range of the subspecies. The descriptions are based on studies conducted by BKS during 2006, 2007, 2012, and 2013 in the vicinity of Sedona, Yavapai County, Arizona (Boynton Canyon, 10 km NW Sedona, UTM 12S 422156E, 3863365N; all NAD 1927) and near Payson, Gila County, Arizona, (including Forest Road 414, 5.6 km SW Payson, UTM 12S 462837E, 3785055N and Houston Mesa Trailhead, 1.6 km NW Payson, UTM 12S 471684E, 3792453N).

At the sites in Gila County, three biomes occur in close proximity, and ecotones between the three blur distinctions easily made in other areas of the state. At elevations of ~1400 to 1800 m, complex mosaics of Great Basin Woodland, Chaparral and Petran Montane Coniferous Forest can be found, with broad to narrow ecotones among the three, resulting in exceptionally high plant diversity relative to typical "pure" stands of these biomes elsewhere. *Aspidoscelis t. punctilinealis* is abundant in these ecotones near Payson, but almost never in pure Chaparral nor pure Woodland nor pure Forest stands. These lizards are especially likely to be present in recently burned areas characterized by newly created open areas with exposed substrate, resulting from both natural and man-made causes. They flourish in these areas as they recover at least for 5-10 years post-burn, with reduced abundance if the community becomes densely vegetated with little exposed substrate (e.g., closed

FIG. 1. Habitat diversity contributing to the presence of *Aspidoscelis tigris punctilinealis* (Sonoran Tiger Whiptail) in the upland (elev. ~1600–1800 m) Houston Mesa area northwest of Payson, Gila County, Arizona showing relatively closed (upper left) and open (upper right) recently burned sites; the granitic boulder site with ample exposed soil (lower left) and the Boynton Canyon area (lower right) near Sedona, Yavapai County, Arizona with a reddish degraded sandstone substrate.

canopy chaparral). Interestingly, as dense Woodland and Forest landscapes are "thinned" to reduce fire risk, available evidence indicates that *A. t. punctilinealis* rapidly colonizes these open structured habitats.

In the vicinity of Houston Mesa situated northwest of Payson (Fig. 1), some vegetation assemblages can be described as lush in a part of Arizona with annual rainfall of ~21.5 inches. *Aspidoscelis t. punctilinealis* is common in what is best termed a Woodland-Chaparral ecotone with plants, in rough order of abundance, to include *Arctostaphylos pungens* (Pointleaf Manzanita), *Quercus turbinella* (Shrub Live Oak), *Mimosa biuncifera* (Wait-a-minute Bush), *Pinus monophylla* (Singleleaf Pinyon Pine), *Juniperus monosperma* (One Seed Juniper), *Cupressus glabra* (Smooth-bark Arizona Cypress), *Quercus emoryi* (Emory Oak), and even *Pinus ponderosa* (Ponderosa Pine) and *Juniperus deppeana* (Alligator Juniper) in small numbers. The soil is primarily graycolored and well-drained, gravelly loam, alluvium of weathered, decomposing granite, with some boulder fields creating open areas devoid of vegetation and abundant thermoregulatory opportunities for squamates (Fig. 1). The only other teiid syntopic with *A. tigris* in these areas is triploid parthenogenetic *A. uniparens* (Desert Grassland Whiptail); *A. velox* (Plateau Striped Whiptail), also a triploid parthenogenetic species, occurs at higher elevations or in pure Great Basin Woodland communities (i.e., exclusive of pinyon/juniper). Other co-occurring saurians with *A. t. punctilinealis* include: *Cophosaurus texanus* (Greater Earless Lizard), *Sceloporus clarkii* (Clark's Spiny Lizard), *Sceleporus tristichus* (Plateau Fence Lizard), *Urosaurus ornatus* (Ornate Tree Lizard), and *Phyrnosoma hernandesi* (Greater Short-horned Lizard). For those who have observed *A. tigris* as the desertscrub teiid, in open creosote flats of the Mohave and Sonoran deserts of the Southwest, these upper elevation habitats are distinct exceptions, more in line with those occupied by *A. t. munda* (California Whiptail) populations found in Coastal Chaparral communities of California. However, *A. t. munda*, like *A. t. punctilinealis*, also inhabits a variety of habitats such as Blue Oak (*Quercus douglasii*) Woodland, *Atriplex-Ephedra* scrublands of the San Joaquin Valley, Panoche Valley, and Carrizo Plain, and Coastal Sage Scrub in southern California.

Near Sedona, Yavapai County, Sonoran Tiger Whiptail was unexpectedly observed along hiking trails with substrate of ample exposed reddish degraded sandstone in canyons and nearby slopes of a similar ecotonal nature to those habitats near Payson. Elements of Great Basin Woodland (e.g., One Seed Juniper, Singleleaf Pinyon Pine), Chaparral (Pointleaf Manzanita, Shrub Live Oak), and Petran Montane Forest (Ponderosa Pine) all co-occur; the lizards there are also associated with relatively open slopes (Fig. 1). It appears that the populations of *A. t. punctilinealis* in these sandstone/canyons with a stunningly reddish substrate (Fig. 1) are derived from the more typical creosote bush habitats occupied along the Verde River to the south.

We thank Elizabeth, Justin, and Keith Sullivan for assistance in the field. Collecting permits were provided by the Arizona Game and Fish Department (20062013, to BKS), and collecting methods were approved as part of IACUC protocols (2006, 2009, and 2011) for surveying and vouchering lizards.

BRIAN K. SULLIVAN, School of Mathematical and Natural Sciences, P.O. Box 37100, Arizona State University, Phoenix, Arizona 85069, USA (e-mail: bsullivan@asu.edu); **JAMES M. WALKER**, Department of Biological Sciences, University of Arkansas, Fayetteville, Arkansas 72701, USA (e-mail: jmwalker@uark.edu).

***BRONCHOCELA CRISTATELLA* (Green Crested Lizard). REPRODUCTION.** *Bronchocela cristatella* ranges from the Nicobar Islands of India, eastward through Myanmar and Thailand and south through Peninsular Malaysia and Singapore, eastward through Papua, Indonesia (Diong and Lim 1998. Raffles Bull. Zool. 46:345–359; Hallermann 2005. Russian J. Herpetol. 12:168–183). There are reports on clutch sizes of 1–4 eggs (Das 2010. A Field Guide to the Reptiles of South-East Asia. New Holland Publishers, London, UK. 376 pp.), 1–2 eggs (Manthey and Grossmann 1997. Amphibien & Reptilien Südostasiens. Natur und Tier – Verlag, Berlin. 512 pp.; Malkmus et al. 2002. Amphibians & Reptiles of Mount Kinabalu [North Borneo]. Koeltz Scientific Books, Königstein, Germany. 424 pp.), and 2 eggs (Cox et al. 1998. A Photographic Guide to Snakes and other Reptiles of Peninsular Malaysia, Singapore and Thailand. New Holland Publishers Ltd, London, UK. 144 pp.). Grismer (2011. Lizards of Peninsular Malaysia, Singapore, and their Adjacent Archipelagos, Their Description, Distribution, and Natural History, Edition Chimaira, Frankfurt am Main. 728 pp.) suggested *B. cristatella* breeds yearround. The purpose of this note is to report additional information on *B. cristatella* reproduction from a histological examination of museum specimens from West Malaysia.

TABLE 1. Monthly stages in the ovarian cycle of 20 adult *Bronchocela cristatella* from West Malaysia: * = 1 female with oviductal eggs was undergoing concurrent yolk deposition for a subsequent egg clutch.

Month	N	Quiescent	Yolk deposition	Enlarged follicles > 5 mm	Oviductal eggs
March	1	0	1	0	0
June	1	0	1	0	0
July	7	3	0	1	3
August	4	0	0	2	2*
September	6	2	2	1	1*
November	1	0	0	0	1*

A sample of 32 *B. cristatella* collected from 2002 to 2006 and from 2008 to 2012 in West Malaysia deposited in the herpetology collection of La Sierra University (LSUHC), Riverside, California, USA, was examined. This series consisted of eleven males (mean SVL = 95.1 mm ± 11.2 SD, range = 73–111 mm), 20 adult females (mean SVL = 96.00 mm ± 7.3 SD, range = 84–109 mm) and one juvenile female (SVL = 72 mm). *Bronchocela cristatella* were collected by West Malaysian state: Johor (N = 14), Kedah (N = 3), Pahang (N = 3), Penang (N = 2), Perak (N = 3), Selangor (N = 5), Serak (N = 1), Terengganu (N = 1).

A cut was made in the lower abdominal cavity and the left testis or ovary was removed, embedded in paraffin, cut into 5-µm sections and stained with Harris hematoxylin followed by eosin counterstain. Enlarged follicles (> 5 mm) or oviductal eggs were counted. Histology slides were deposited in LSUHC.

Two stages were observed in the testicular cycle: 1) spermiogenesis, seminiferous tubules are lined by sperm, or clusters of metamorphosing spermatids; 2) regressed, seminiferous tubules are reduced in size and contain spermatogonia and interspersed Sertoli cells. Males were undergoing spermiogenesis in the following months: July (N = 3), August (N = 6), September (N = 1). One male of adult size (SVL = 94 mm) contained a regressed testis (LSUHC 5673). Our male sample sizes are too small to speculate on the significance of this single male with a regressed testis in the yearly male reproductive cycle. The smallest reproductively active male (spermiogenesis) measured 73 mm SVL (LSUHC 6543) and was collected in August.

Four stages were observed in the ovarian cycle (Table 1): 1) quiescent (no yolk deposition); 2) early yolk deposition (basophilic yolk granules in ooplasm); 3) enlarged pre-ovulatory follicles (> 5 mm); 4) oviductal eggs. Mean clutch size (N = 11) was an invariant 2.0. Three females (Table 1) with oviductal eggs were undergoing concurrent yolk deposition for a subsequent clutch indicating *B. cristatella* produces multiple clutches in the same year. The smallest reproductively active female exhibited yolk deposition, measured 84 mm SVL (LSUHC 10660), and was collected in June. One smaller female (SVL = 70 mm) had very small, inactive ovaries and was considered to be a juvenile (LSUHC 10647).

In conclusion, from the presence of female reproductive activity at opposite ends of the year it is apparent *B. cristatella* exhibits an extended reproductive cycle as do other lizards from southern Asia (see Inger and Greenberg 1966. Ecology 47:1007–1021). Our report contains the first data indicating *B. cristatella* produces multiple clutches in the same year.

STEPHEN R. GOLDBERG, Natural History Museum of Los Angeles County. Herpetology Section, Los Angeles, California 90007, USA (e-mail: sgoldberg@whittier.edu); **L. LEE GRISMER,** La Sierra University, Department of Biology, Riverside, California 92515, USA (e-mail: lgrismer@lasierra.edu).

***CYRTODACTYLUS MACROTUBERCULATUS* (Tuberculate Bent-toed Gecko). REPRODUCTION.** *Cyrtodactylus macrotuberculatus* was recently described by Grismer and Norhayati 2008 (Zootaxa 1924:53–68) from Kedah, West Malaysia and has unofficially been reported from southern Thailand (Grismer 2012. et. al. Zootaxa 3520:1–55). Grismer (2011. Lizards of Peninsular Malaysia, Singapore and their Adjacent Archipelagos. Edition Chimaira, Franfurt am Main. 728 pp.) reported a gravid female with two eggs during September from Perlis state and hatchlings during March, August, and September, suggesting year-round breeding. The purpose of this note is to add information on the reproductive biology of *C. macrotuberculatus*.

Table 1. Monthly stages in the ovarian cycle of seven adult female *Cyrtodactylus macrotuberculatus* from West Malaysia.

Month	N	Quiescent	Early yolk deposition	Enlarged follicles > 5 mm	Oviductal eggs
March	3	1	1	0	1
June	1	0	0	0	1
August	1	0	1	0	0
September	2	0	0	2	0

A sample was examined consisting of 24 *C. macrotuberculatus* collected in West Malaysia during 2004, 2008–2012 deposited in the herpetology collection of La Sierra University, Riverside, California, USA (LSUHC), consisting of eight adult males (mean SVL = 94.0 mm ± 10.4 SD, range = 74–103 mm), seven adult females with quiescent ovaries (mean SVL =106.0 mm ± 4.6 SD, range = 97–109 mm), four sub-adult females (mean SVL = 80.0 ± 7.5 SD, range = 72–89 mm), and five unsexed juveniles (mean SVL = 50.0 mm ± 10.1 SD, range = 44–68 mm). *Cyrtodactylus macrotuberculatus* collected by West Malaysian states were: Kedah (LSUHC) 6829, 7532, 7560, 8334–8337, 9133, 9429, 9432, 9448–9450, 9671–9673, 9693, 10579 and Perlis (LSUHC) 9686, 9687, 9980, 9981, 10037, 10067.

A cut was made in the lower abdominal cavity and the left testis or ovary was removed, embedded in paraffin, cut into 5-µm sections and stained with Harris hematoxylin followed by eosin counterstain. Enlarged follicles (> 4 mm) or oviductal eggs were counted. Histology slides were deposited in LSUHC.

The only stage present in the testicular cycle was spermiogenesis in which the lumina of the seminiferous tubules were lined by sperm or clusters of metamorphosing spermatids. The smallest reproductively active male measured 74 mm SVL (LSUHC 8335) and was collected in March. Monthly distribution of spermiogenic males was: March (N = 4), May (N = 1), June (N = 1), September (N =1), November (N = 1).

Four stages were present in the monthly ovarian cycle (Table 1): 1) quiescent, no yolk deposition; 2) yolk deposition, basophilic yolk granules in the ooplasm; 3) enlarged follicles > 4 mm; 4) oviductal eggs. The smallest reproductively active female measured 97 mm SVL (LSUHC 8337), contained two oviductal eggs, and was collected in June.

Mean clutch size (N = 4) was 1.5 ± 0.58 SD, range 1–2). There was no indication of females producing multiple clutches, as no female with oviductal eggs and concurrent yolk deposition was found which would have indicated production of a subsequent clutch, however this likely reflects our small female sample size.

The presence of reproductive activity in all months sampled indicates *C. macrotuberculatus* exhibits an extended breeding cycle as do other South Asian lizards. See for example, Inger and Greenberg (1966. Ecology 47:1007–1021) and Grismer (2011, *op. cit.*).

STEPHEN R. GOLDBERG, Natural History Museum of Los Angeles County, Herpetology Section, Los Angeles, California 90007, USA (e-mail: sgoldberg@whittier.edu); **L. LEE GRISMER,** La Sierra University, Department of Biology, Riverside, California 92515, USA (e-mail: lgrismer@lasierra.edu).

***DASIA OLIVACEA* (Olive Tree Skink). REPRODUCTION.** *Dasia olivacea* ranges from Myanmar eastward to Vietnam and south through the Malay Peninsula and Singapore to Sumatra, Java, Borneo, and some adjacent islands (Inger and Brown 1980. Field. Zool. 3:1–11). There are accounts of *D. olivacea* clutch sizes in Das (2010. A Field Guide to the Reptiles of South-East Asia, Myanmar, Thailand, Laos, Cambodia, Vietnam, Peninsular Malaysia, Singapore, Sumatra, Borneo, Java, Bali. New Holland Publishers, London. 376 pp.; 6–14 eggs) and Manthey and Grossmann (1997. Amphibien & Reptilien Südostasiens. Natur und Tier – Verlag, Berlin. 512 pp.; 9–14 eggs). *Dasia olivacea* females may produce clutches three to four times a year (Malkmus et al. 2002. Amphibians & Reptiles of Mount Kinabalu [North Borneo]. Koeltz Scientific Books, Königstein, Germany. 424 pp.). In this note we report additional information on reproduction of *D. olivacea* from West Malaysia from a histological examination of museum specimens.

A sample of 19 *Dasia olivacea* from West Malaysia collected 2001 to 2006, 2009, and deposited in the herpetology collection of La Sierra University (LSUHC), Riverside, California, USA, was examined. The sample consisted of six adult males (mean SVL = 95.5 mm ± 8.6 SD, range = 80–103 mm), eight adult females (mean SVL = 87.3 mm ± 5.9 SD, range = 80–98 mm), one subadult male (SVL = 73 mm), two subadult females (mean SVL = 72.5 mm ± 0.70 SD, range = 72–73 mm), two unsexed juveniles (mean SVL 42.5 mm ± 13.4 SD range = 33–52 mm SVL). *Dasia olivacea* were collected in West (Peninsular) Malaysia (by state): Johor (N = 8), Kedah (N = 4), Pahang (N = 4), Terengganu (N = 3).

A cut was made in the lower abdominal cavity and the left testis or ovary was removed, embedded in paraffin, cut into 5 µm sections and stained with Harris hematoxylin followed by eosin counterstain. Enlarged follicles (> 4 mm) or oviductal eggs were counted. Histology slides were deposited in LSUHC.

The predominant stage present in the testicular cycle was spermiogenesis in which the seminiferous tubules are lined by clusters of sperm or metamorphosing spermatids. The smallest reproductively active male (spermiogenesis in progress) measured 80 mm SVL (LSUHC 5600) and was collected in July. Other mature males were collected in July (N = 3), August (N = 1), September (N = 1). One smaller male (SVL = 73 mm) contained a regressed testis in which the seminiferous tubules contained spermatogonia and interspersed Sertoli cells (LSUHC 8023). Goldberg (2012. Hamadryad 36:51–53) reported males of the congener *D. vittata* from Borneo exhibited spermiogenesis during all nine months samples were examined.

Four stages were observed in the ovarian cycle of *D. olivacea* (Table 1): 1) quiescent (no yolk deposition); 2) early yolk deposition (basophilic yolk granules in ooplasm); 3) enlarged pre-ovulatory ovarian follicles > 4 mm; 4) oviductal eggs. Mean clutch size (N = 3) was 6.33 ± 1.2 SD, range = 5–7. The smallest reproductively active female (early yolk deposition) measured 83 mm SVL (LSUHC 7576) and was collected in August. Two smaller females (SVL 72, 73) contained very small quiescent ovaries (LSUHC 7495, 9367). The *D. olivacea* reproductive period includes August and September. We lack monthly samples of *D. olivacea* to ascertain the duration of the reproductive period. However, females of the congener *D. vittata* from Borneo exhibited reproductive activity in all months of the year except for December, from which only one female was available (Goldberg, *op. cit.*). Five is a new minimum clutch size for *D. olivacea*.

Table 1. Monthly stages in the ovarian cycle of eight adult *Dasia olivacea* females from West Malaysia.

STEPHEN R. GOLDBERG, Natural History Museum of Los Angeles County, Herpetology Section, Los Angeles, California, USA: (e-mail: sgoldberg@whittier.edu); **L. LEE GRISMER,** La Sierra University, Department of Biology, Riverside, California 92515, USA; (e-mail: lgrismer@lasierra.edu).

***HEMIDACTYLUS FRENATUS* (Asian House Gecko). PREY.** *Hemidactylus frenatus* is primarily an oriental species, but has spread (often human-mediated) pantropically and its introduced range currently includes parts of South-East Asia, Japan, parts of Central America, Mexico, some localities in southern USA, Madagascar, parts of Africa, Australia, and many islands of the Pacific, Indian, and Atlantic oceans (Case et al. 1994. Ecology 75:464–477; Rödder et al. 2008. North-Western J. Zool. 4:236–246; Hoskin 2011. Austral Ecol. 36:240–251). In Taiwan, this gecko species occurs at altitudes below 1000 m island-wide and on the outlying islets (Lue et al. 2002. The Transition Kingdom — Guidebook of Amphibians and Reptiles of Taiwan. SWAN, Taipei, Taiwan. 347 pp. [in Chinese]).

At ca. 1950 h on 20 August 2013, while preparing the rooftop garden of his residence in Yilan City, northeastern Taiwan (24.7505556°N, 121.7613889°E, datum WGS84; elev. 13 m) for Typhoon Trami that was expected to pass the area the next day, JJM disturbed a resting Globe Skimmer (*Pantala flavescens*) when he turned on an outdoor light. The insect flew to the light, where it was grasped by the head by an adult *H. frenatus* that was sheltering behind the light (Fig. 1). The observations were discontinued at ca. 2030 h, at which point the gecko was still trying to ingest the dragonfly.

Both within its native range and areas where it has been introduced, *H. frenatus* is a nocturnal species that is often attracted to indoor and outdoor lights in areas disturbed by anthropogenic activities, where they can easily feed on insects that are also attracted to the lights (Newberry and Jones 2007. *In* Lunney et al. [eds.], Pest or Guest: The Zoology of Overabundance, pp. 59–65. Royal Zoological Society of New South Wales, Sydney, Australia); Vanderduys and Kutt 2012. Austral. J. Zool. 60:361–367). For such a small lizard, the adults of *H. frenatus* appear to be adept at preying on relatively large prey items. There have been reports of individuals preying on conspecific hatchlings, the hatchlings and juveniles of *Lepidodactylus lugubris*, as well as on *Nactus coindemirensis* of unknown sizes (McCoid and Hensley 1993. Herpetol. Rev. 24:87–88; Cole et al. 2005. Biol. Conserv. 125:467–474). Petren and Case (1996. Ecology 77:118–132) also noted that *H. frenatus* males, in particular, are good at preying on large roaches, and we have observed an adult *H. frenatus* preying on an adult American Cockroach (*Periplaneta americana*) (Norval and Mao 2013. IRCF Reptiles & Amphibians. 20:140–142). The dragonfly described herein is thus yet another example of a relatively large prey item captured, and presumed consumed, by an adult *H. frenatus*. However, because dragonflies are diurnal and alert insects, they are unlikely typical prey for *H. frenatus*. Nevertheless, in some instances dragonflies are attracted to

PHOTOGRAPH BY JEAN-JAY MAO

outdoor lights in residential areas, especially if the residential area is located near a wetland or prior to rains (JJM and GN, pers. obs.), and under such conditions predation on dragonflies by geckos is possible, as reported herein. The observations described herein therefore not only again raise the question of size and shape limits of prey that can be utilized by *H. frenatus*, but also highlight the opportunistic nature of these lizards.

***IGUANA IGUANA* (Common Green Iguana). PREDATION.** *Oxybelis fulgidus* is an arboreal snake widely distributed in the Americas, occurring from Mexico to tropical South America (Peters and Orejas-Miranda 1970. Bull. U.S. Nat. Mus. 297:1–347). This species has been described as a sit-and-wait predator that feeds mainly on lizards (*Ameiva, Anolis, Basiliscus, Ctenosaura, Mabuya, Polychrus, Sceloporus,* and *Tropidurus* [Scartozzoni et al. 2009 S. Am. J. Herpetol. 4:81–89]) and birds (Fraga et al. 2012 Herpetol. Rev. 43:495–496). In this report we present a new genus of lizard in the diet of *O. fulgidus.*

During the afternoon at 1729 h on 25 June 2012, an *O. fulgidus* was collected at the municipality of Serra do Navio (0.900833°N, 52.013472°W, datum WGS84), on the right bank of the Amapari River, Amapá, Brazil. The individual was killed by local inhabitants and the stomach was partially open containing a juvenile *Iguana iguana.* The snake was an adult female with a SVL of 498 mm, tail length of 245 mm,and head length of 24.9 mm. The iguana measured 128 mm SVL, 296 mm tail length, 25.8 mm head length. This is another record of an iguanid lizard in the diet of *O. fulgidus,* and the first recorded predation of *I. iguana* by this snake.

SOUSA VALENTIM** (e-mail: daniellvalemtimm@gmail.com), **MAYARA F. MELO FURTADO** (e-mail: mayarafabiana@gmail.com), and **LIEGE C. ARRUDA** (e-mail: liegecoutinho@yahoo.com.br), Laboratório de Herpetologia, Departamento de Ciências Biológicas e da Saúde, Universidade Federal do Amapá, Campus Marco Zero, 68.903-419, Macapá, AP, Brazil.

***LACERTA SCHREIBERI* (Schreiber's Green Lizard). NATURAL NEST.** Data on *in situ* female nest site selection in Iberian lizards is lacking, while such information is crucial to complement experimental results obtained by captive breeding. Specifically, studies that relate elevational range limits with incubation requirements are in need of validation by information pertaining to nesting locations in the field (Monasterio et al. 2011. Ecography 34:1030–1039). In fact, it is likely that the distribution of *Lacerta schreiberi* is constrained by available thermal conditions for nesting (Monasterio et al. 2013. J. Zool. 291:136–145), and thus, information on natural nest sites is most useful. However, very few observations have been recorded in the wild (Galán 1989. Treb. Soc. Cat. Ictio. Herpetol. 2:250–265). We encountered a single nest of *L. schreiberi* by turning a stone (56 cm × 30 cm × 5–10 cm thickness), while surveying reptiles at the summit of Peña Negra, Spain (40.417534°N, 5.304219°W, elev. 1936 m) on 21 June 2013 (Fig. 1A). The clutch consisted of 13 eggs that were half buried into the ground, but sheltered by the stone. A female was observed next to the nest (i.e., also sheltered by the stone before it was turned), which was totally covered by soil, suggesting that she had very recently laid the eggs. The presence of the female permitted the identification of the eggs. The surrounding habitat consisted of mixed shrubs and large boulders (Fig. 2A), typical for high elevation areas in the Sistema Central Mountain Range.

Such observations as we report here are needed to choose adequate methodology to measure temperature availability for nesting, as well as to validate previous work (i.e., burying loggers under rocks or bare ground at 5 cm depth; Monasterio et al. 2013, *op. cit.*) due to the hitherto total lack of information about female nest site selection in *L. schreiberi.*

FIG. 1. Egg clutch (*in situ*) of *Lacerta schreiberi* (A), and the surrounding habitat (B). The arrow indicates the stone under which the clutch was encountered.

***PHRYNOSOMA ASIO* (Giant Horned Lizard). CREPUSCULAR AND NOCTURNAL ACTIVITY.** *Phrynosoma asio* is currently distributed in the physiographic provinces of the Balsas-Tepalcatepec Depression and Sierra Madre del Sur (Alvarado-Díaz et al. 2013. Amphib. Rept. Conserv. 7:128–170) It is generally considered to be a diurnal lizard, however, Pianka and Parker (1975. Copeia 1975:141–162) found that the activity time of the members of the genus *Phrynosoma* is variable (i.e., they are typically active earlier and later, and over a longer time span, than most other sympatric species of lizards). Williams (1959. Herpetologica 1:43) established that the majority of the horned lizards are strictly diurnal and are only facultatively nocturnal in response to environmental disturbances and certain thermal conditions. The genus *Phrynosoma* is not physiologically adapted to be a nocturnal animal; in fact it has been demonstrated that their eyes are adapted for diurnal use (Crozier and Wolf 1941. J. Gen. Physiol. 24:317–324). However, in the presence of sufficient light, these lizards can perform certain activities, such as feeding (Milde and Milde 1950. Amer. Midl. Nat. 3:720–741) or even make use of the moonlight to perform activities such as copulation (Lara-Resendiz et al. 2013. Herpetol. Rev. 44:326–327). Here I report the first observation and record of *P. asio* conducting crepuscular and nocturnal activity in Michoacán, México.

During 21 August 2010, while studying the habitat selection of *Phrynosoma asio*, I recorded a gravid adult female (SVL = 94 mm, total length = 150 mm, and weight = 200 g) at 1915 h with crepuscular activity after sunset near a hole (ca. 20 cm in diameter) under a paloverde tree (*Cercidium* sp.) that appeared to be a refuge used by the lizard. The habitat was disturbed with secondary vegetation consisting mainly of xeric shrublands and cacti (*Pachycereus* sp.) near human settlements in the locality Nuevo Centro municipality of La Huacana, Michoacán, México (18.739113°N, 102.009915°W; 211 m elev). This individual tried to escape into the hole but was captured. Data were collected on microhabitat, temperature, and humidity: substrate temperature 33.7°C, air temperature 33.5°C, substrate humidity 72%, air humidity 84%. The distance to the nearest anthill was 12.9 m.

On 29 May 2010, a juvenile female *P. asio* (SVL = 69 mm, total length = 111 mm, weight = 12.7 g) was seen at 2020 h among grasses; when it was illuminated with a lamp, it started to feed on nocturnally active black ants (unidentified species) near the edge of a dry creek (18.733423°N, 102.006502°W; 173 m elev.). I recorded microhabitat data on a square meter from which the lizard was collected: substrate temperature 32.8°C, air temperature 33.2°C, substrate humidity 23.7%, air humidity 25.5%. The distance to the nearest anthill was 16 m.

These observations suggest two things; the first and most interesting is that the presence of light, be it natural or artificial, plays an important role in the delimitation of activity of *P. asio* within its environment and may aid in activities such as feeding. Second is the possibility that *P. asio* sometimes does not complete its daily activities at the termination of daylight, resulting from extremely high daytime temperatures. Therefore, recourse to seize the last hours of light after sunset may help to complete their foraging or other biological activity requirements. In addition, this might be possible as a result of the artificial lighting produced at night by nearby human settlements. Finally, it would be interesting to investigate whether such behaviors are also observed at other localities inhabited by *P. asio* with similar or different thermal and anthropological conditions and establish whether or not these are adaptive responses.

I thank Ireri Suazo Ortuño for funding and providing field equipment and advice. Thanks to Jonatan Torres Pérez Coeto and Oscar Medina Aguilar for their help in the field and the Reyes-Solorio family for hosting me in their home and for guiding me in the field.

ERNESTO RAYA-GARCÍA, Instituto de Investigaciones sobre los Recursos Naturales, Laboratorio de Herpetología, Universidad Michoacana de San Nicolás de Hidalgo, C.P. 58000, Morelia, Michoacán, México; e-mail: tuataraya@hotmail.com.

***PHYLLOPEZUS POLLICARIS* (Brazilian Gecko, Lagartixa). HATCHLING SIZE/BEHAVIOR.** The nocturnal gecko *Phyllopezus pollicaris* (Phyllodactylidae) is widely distributed along the South American great diagonal of open formations (Cerrado, Caatinga, and Chaco) to the coastal Atlantic Forest of northeastern Brazil, and is composed of multiple cryptic lineages (Gamble et al. 2012. Mol. Phylog. Evol. 62:943–953; Werneck et al. 2012. Evol. 66:3014–3034; Recoder et al. 2012. Herpetol. Notes 5:49–58). In many areas, the reproductive activity of *P. pollicaris* is cyclic, occurring from the end of the dry season to the end of the wet season, and gravid females usually have two oviductal eggs (Righi et al. 2012. J. Herpetol. 46: 632–636; Recoder et al. 2012, *op. cit.*). In some Caatinga areas, females appear to produce eggs continuously throughout the year (Vitt 1986. Copeia 1986:773–786). There is little published information about the life history and reproduction of this species.

On 9 October 2013 we collected three eggs of *P. pollicaris* from Brumado, Bahia state, Brazil, located within Caatinga domain (14.203889°S, 41.665278°W; 422 m elev.). The three eggs were in a communal nest under the leaf litter. After being brought to our laboratory, the eggs were placed and maintained in a terrarium in a sand substrate next to a window protected from direct solar radiation, but we made no effort to otherwise control light or temperature; incubation occurred under ambient conditions. Ambient temperatures varied from 13ºC to 31ºC during October and early November 2013. We measured the eggs and surviving hatchlings with a digital caliper (± 0.01 mm) for snout–vent length (SVL) and tail length (TL).

We recorded hatchling emergence of two eggs on 11 November 2013, and the other egg remained unhatched. The sizes of the three eggs were 11.4 × 9.18 mm, 11.71 × 9.38 mm, and 12.80 × 10.15 mm. The first lizard hatched had a SVL = 24.85 mm and TL = 26.82 mm, and the second one had a SVL = 24.79 mm and TL = 26.01 mm. The minimum SVL of these newly hatched geckos were different from those reported by Vitt (1986, *op. cit.*) (SVL = 29 mm) in Exu,

FIG. 1. Newly hatched *Phyllopezus pollicaris* (UFMG 1918) after removing and ingesting shed skin.

Pernambuco state, Brazil, and that found by Recoder et al (2012, *op. cit.*) (SVL = 34.1 mm) in Tocantins state, northern Brazil. Egg sizes were also different from those reported by Vitt (1986, *op. cit.*; N = 12; mean = 13.07 ± 0.34 mm length; mean = 9.38 ± 0.25 mm width). Presumably because of the high climatic unpredictability of the Caatinga (Colli et al. 2003. J. Herpetol. 37:694–706), reproductive parameters of *P. pollicaris* could be affected. In *P. pollicaris* clutch size is always two (Vitt 1986, *op. cit.*; Ávila and Cunha-Avellar 2005. Herpetol. Rev. 36:453–454); therefore, the eggs collected by us probably are evidence of communal oviposition, what seems to be normal for the genus (Vitt 1986, *op. cit.*; Righi et al. 2004. Herpetol. Rev. 35:395–396; Ávila and Cunha-Avellar 2005, *op. cit.*; Lima et al. 2011. Salamandra 47:227–228). The specimens reported here represent a new record for minimum body size for *P. pollicaris* juveniles.

After hatching, one of the neonate lizards ingested its own skin (Fig. 1). This behavior likely provides an extra source of nutrients as noted for other lizard taxa (Bustard and Maderson 1965. Herpetologica 21:306–308). To our knowledge, this is the first reported occurrence of this behavior in *Phyllopezus*.

The *P. pollicaris* specimens (UFMG 1918, 1920) were deposited in the Herpetological Collection of Universidade Federal de Minas Gerais. We are grateful to CAPES for doctorate fellowships awarded to SCG.

SAMUEL CAMPOS GOMIDES (e-mail: samuelbio@hotmail.com) and **PAULO CHRISTIANO DE ANCHIETTA GARCIA** (e-mail: pcagarcia@gmail.com), Programa de Pós-Graduação em Zoologia, Departamento de Zoologia, Instituto de Ciências Biológicas, Universidade Federal de Minas Gerais, Av. Antônio Carlos, 6627, CEP 31270-901, Belo Horizonte, MG, Brazil.

***PLESTIODON FASCIATUS* (Five-lined Skink). SPIDER WEB ENTRAPMENT.** There are numerous examples in the literature of lizards being eaten by spiders (e.g., Whiting et al. 1991. Herpetol, Rev. 22:58; Hamilton 2011. Herpetol. Rev. 42:603; Lazcano et al. 2012. Herpetol. Rev. 43:37–138). However, reports of lizards being entrapped by spider webs are relatively uncommon. Lizards have been found in the webs of spiders in the families Araneidae (Lazell 1995. Herpetol. Rev. 26:205; Mitchell and Ruckdeschel 2013. Herpetol. Rev. 44:136–137), Nephilidae (Filipiak and Lewis 2012. Herpetol. Rev. 43:486), and Theridiidae (Colombo 2013. Herpetol. Rev. 44:320–321; García-Roa et al. 2013. Herpetol. Rev. 44:147; Painter and Kamees 2010. Herpetol. Rev. 41:227). To our knowledge, this is the first report of a lizard becoming entrapped in the web of a spider in the family Tetragnathidae.

On 10 August 2013, two of us (MV and MWHC) observed a juvenile *P. fasciatus* in the web of a male Long-jawed Orb Weaver (*Tetragnatha* sp., Tetragnathidae) beneath a low concrete bridge spanning Lees Creek near the town of Bogalusa in Washington Parish, Louisiana, USA (30.7218°N, 89.8658°W; datum WGS84). The skink was alive, although somewhat unresponsive, with its hind right limb severely entwined in the web. The spider was present on the web and positioned approximately 20 cm away at the time of discovery. The spider was captured and preserved for identification.

CHATFIELD, Tulane-Xavier Center for Bioenvironmental Research, Tulane University, New Orleans, Louisiana 70118, USA (e-mail: mattchat@tulane.edu); **MATT VANCE**, Louisiana Outdoor Outreach Program, Office of State Parks, New Orleans, Louisiana 70124, USA (e-mail: mvance@crt.la.gov); **AIMÉE K. THOMAS**, Department of Biological Sciences, Loyola University, New Orleans, Louisiana 70118, USA (e-mail: akthomas@loyno.edu); **JAMES R. LEE**, The Nature Conservancy, CSJFTC-ENV Building 6530, Camp Shelby, Mississippi 39407, USA (e-mail: jlee@tnc.org).

***PLICA PLICA* (Tree Runner) and *PLICA UMBRA* (Blue-lipped Tree Runner). MORPHOLOGICAL ANOMALIES.** Many morphological malformations have been reported in lizards. Structural anomalies and teratogenic defects resulting in unusual appendages and tissue growth are known to occur sporadically among reptiles and

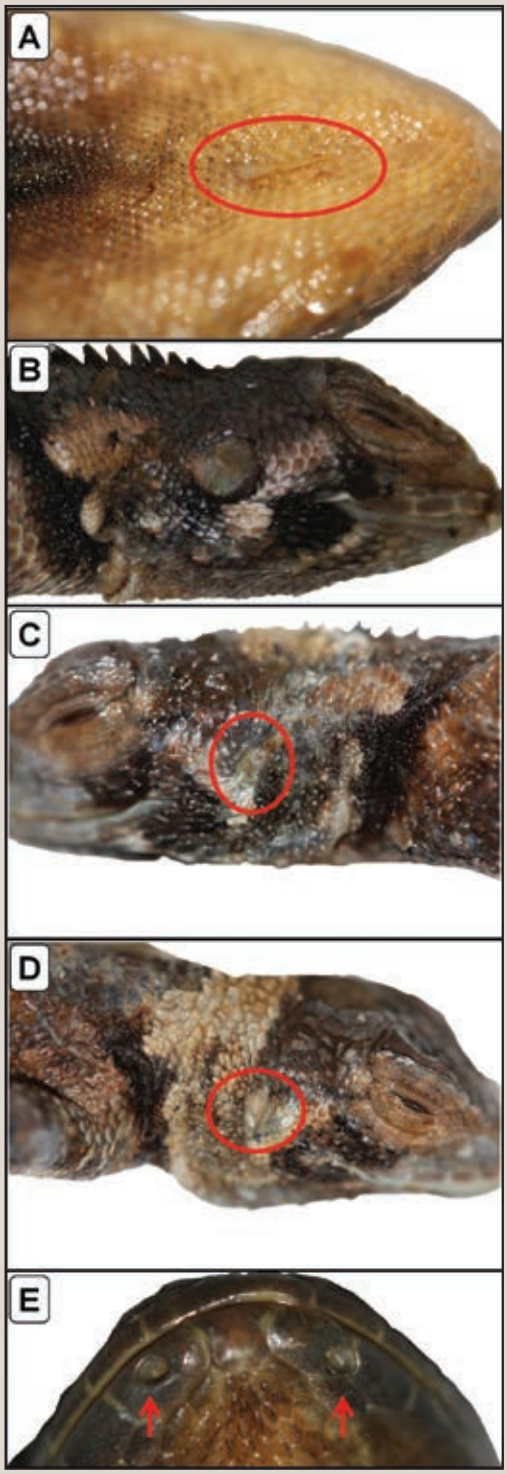

FIG. 1. A) *Plica plica* (MPEG LAG 2612) with a filiform appendix in gular region; B) a normal ear opening in *P. umbra* (MPEG LAG 11278); *P. umbra* (MPEG LAG 11279) with an anomalous ear opening in the left side C) and the right side D); and E) a *P. umbra* (INPA 0006) with symmetrical cavity in the first infralabial scales

amphibians throughout the world (see Chan et al. 1984. Hawaii Volcanoes National Park: Proceedings of the Fifth Conference of National Science, pp. 41–50; Owens and Knapp 2007. Herpetol. Rev. 38:454–455; Gogliath et al. 2012. Herpetol. Rev. 43:129; Avila et al. 2013. Herpetol. Rev. 44:144–145; Conzendey et al. 2013. Herpetol. Rev. 44:145–146; and citations therein). *Plica plica* and *P. umbra* are lizards restricted to the Amazonian rainforest and usually live on tree trunks, although they can occasionally be spotted on shrubs, fallen logs, sleeping on leaves or on the ground (Ávila-Pires 1995. Zool. Verh. Leiden. 1995:1–706).

During a taxonomic study on these lizards, we obtained specimens in the field with some morphological abnormalities that we report for the first time here. The specimens examined are housed in the Museu Paraense Emilio Goeldi (MPEG) and in the Instituto Nacional de Pesquisas da Amazônia (INPA). One of the lizards examined, a male *P. plica* (MPEG LAG 2612; 101.5 mm SVL) from Mazagão, Amapá state, Brazil (0.115°S, 51.288889°W), had a filiform appendix in the gular region (Fig. 1A). A male *P. umbra* (MPEG LAG 11279; 74 mm SVL) from Nova Vida, Maranhão state, Brazil (1.827669°S, 46.100781°W) had a malformation of the ear opening (1C and D). The ear opening is reduced to a small slit (1.5 mm diam) on the right side, and an almost absent opening on the left side. Another male *P. umbra* (INPA 0006; 95.3 mm SVL) examined from UHE Cachoeira Porteira, Oriximiná, Pará state, Brazil (1.440000°S, 56.523889°W), had a symmetrical cavity on the first infralabial scales (Fig. 1E). It is unknown if these abnormalities decreased probability of survival in these lizards, though these specimens had reached adult size and otherwise appeared to be in good health. However, it is also clear that visual, olfactory, and auditory cues are very important to lizards (Chou et al. 1988. J. Herpetol. 22:349–351; Oliver and Hutchinson 2009. Herpetol. Rev. 2009. 40:414–415).

To our knowledge, this is the first report of these conditions in *Plica*. We conclude that these abnormalities are of long-standing condition and may be the result of a congenital defect or defective development at an early stage.

We are grateful to Ana Lúcia da Costa Prudente and Richard Vogt for making facilities available and permitting access to the Museu Paraense Emílio Goeldi and Instituto Nacional de Pesquisas da Amazônia, respectively. We thank CAPES for doctorate fellowships awarded to SCG and to CNPq and FAPESP.

***PODARCIS ERHARDII* (Erhard's Wall Lizard). BIFURCATED TAIL, POST-AUTOTOMY.** While conducting fieldwork in the Aegean Islands, we came across an Erhard's Wall Lizard with a forked tail. This phenomenon, though not novel, has never been formally documented in this species.

Many lizards rely on caudal autotomy (tail shedding) to escape predation. The tail separates from the body along an intravertebral breakage plane close to the point of attack (Bateman and Fleming 2009. J. Zool. 277:1–14). After autotomization has occurred, the severed tail writhes for several minutes (up to 14 minutes in *P. erhardii*), presumably distracting the predator (Pafilis et al. 2005. Physiol. Biochem. Zool. 78:828–838). In addition, there is some evidence that shedding a bitten tail that has been injected by venom may help avoid lethal exposure to viper predation (Pafilis et al. 2009. Evolution 63:1262–1278). Nevertheless, tail shedding also has important costs, including elevated stress hormone levels (Langkilde and Shine 2006. J. Exp. Biol. 209:1035–1043), as well as declines in social status and reproductive fitness (Simou et al. 2008. Copeia 2008:504–509).

FIG. 1. *Podarcis erhardii* with a post-autotomized, bifurcated tail.

The lizard we observed was found on Gaiduronissi Islet (off NE Paros Island, Cyclades Pref., Aegean Sea, Greece). This uninhabited islet is quite small (< 1 km^2), has limited food availability, yet high lizard density compared to other Cycladic islands of its size (12 lizards per 100 m transect). Gaiduronissi does not harbor vipers, which have been implicated in elevated autotomy rates in the Greek Archipelago (Pafilis et al. 2009, *op. cit.*). We hypothesize the two-tailed individual had experienced an aggressive encounter either with a predator (Black Rat, *Rattus rattus*, the only predatory vertebrate on this island) or a conspecific, and had autotomized its tail. At some point during the regeneration process, the lizard must have again autotomized, this time only partially. Physiological cues triggered tail regrowth at the site of injury despite the incomplete autotomy, thus leaving the lizard with two tails. The bifurcated tail differs morphologically from the base of the tail (Fig. 1): the original unautotomized base of the tail displays the original scalation pattern, while the newly regenerated tail is discolored and does not follow the black striped pattern. These external differences in appearance extend to internal morphology; regenerated tails contain cartilage rather than calcified vertebrae, making this observation especially odd because regenerated tails do not have breakage planes (Bateman and Fleming, *op. cit.*). The specimen was deposited in the Michigan Museum of Zoology Herpetology Division collection (acquisition ID: 20026).

While possessing the ability to shed a body part grasped by an enemy is a powerful and effective escape strategy, having two tails is likely to be disadvantageous to the individual. In addition to potentially being more conspicuous to predators, a lizard with two tails possibly experiences decreased locomotory performance compared to its one-tailed conspecifics.

KINSEY M. BROCK (e-mail: kbkinsey@umich.edu), **ANAT BELASEN** (email: abelasen@umich.edu), and **JOHANNES FOUFOPOULOS** (e-mail: jfoufop@umich.edu), School of Natural Resources and Environment, 440 Church Street, University of Michigan, Ann Arbor, Michigan 48109, USA.

***TILIQUA MULTIFASCIATA* (Centralian Bluetongue Lizard). PREDATION.** *Tiliqua multifasciata* is a large lygosomine scincid lizard widespread across much of the northern half of continental Australia except the far north, from the west coast to central western Queensland and the northwest corner of New South Wales (Shea and Peterson 1981. Aust. J. Herpetol. 1:27–28; Shea 1992. The Systematics and Reproduction of Bluetongue Lizards of the Genus *Tiliqua* (Squamata: Scincidae). 4 Volumes. Unpubl. Ph.D. Thesis, University of Sydney, Sydney, N.S.W. v + 1053 pp. + 167 pp.; Cogger 2000. Reptiles and Amphibians of Australia [6th ed.]. Reed New Holland, Sydney. 808 pp.; Shea 2000. *In* Hauschild et al. [eds.], Blauzungenskinke. Beitrage zu *Tiliqua* und *Cyclodomorphus*, pp. 108–112. Natur und Tier Verlag, Munster, Germany). Few records of its predators exist. This note documents an observation of predation on *T. multifasciata* by a Little Eagle, *Hieraaetus morphnoides* (Accipitriformes: Accipitridae: Accipitrinae).

At ca. 1210 h (Australian Western Standard Time) on 5 April 2012, MP observed an adult dark morph *H. morphnoides* sitting on an upper branch of a ca. 7 m high *Acacia aneura* (Mimosaceae) tree ca. 4 m above the ground, on an upland plateau in the upper Fortescue River drainage, ca. 110 km west-northwest of Newman, northern Pilbara region, northwest Australia (22.803033°S, 118.86225°E, datum WGS84; 706 m elev.); beneath the feet of the eagle was a freshly killed adult *T. multifasciata* draped venter-uppermost over the branch (Fig. 1); total length of the carcass was estimated at ca. 25 cm (not collected). The *T. multifasciata* had been nearly decapitated, with the head attached by only a thin band of skin draped over the branch; the throat had been opened, exposing the tongue, and the left body opened ventrolaterally, with the forelimbs and most of the viscera removed, hence feeding had commenced and was largely completed, although the hindlimbs and tail were still intact. The *H. morphnoides* continued to pick at the carcass during early observations, but flew off to another tree ~200 m distant on approach of observers to within 50 m for closer photography. Habitat was a damp red-brown clay floodplain with surface ironstone pebbles and stones, supporting a sparse woodland comprised of scattered tall *Acacia* spp. and *Corymbia* spp. trees with an open *Triodia pungens* hummock grassland understorey; air temperature was ca. 25°C, with some high diffuse cloud cover and no wind.

Hieraaetus morphnoides occurs over all of mainland Australia (absent from Tasmania) and some large northern offshore islands. It is typically known as a predator of small to medium sized mammals and birds, however reports of predation on reptiles are sparse (e.g., at Armidale, N.S.W., eastern Australia, prey items at 3 nests mammals 60%, birds 25%, lizards 15%, in fecal pellets mammals 55%, birds 25%, lizards 20%, Debus 1984. Emu 84:87–92), and as far as we are aware this is the first record of predation by this raptor on *T. multifasciata*, although a predation attempt on a *T. multifasciata* by an Australian raptor recorded as a predator of several species of snakes and lizards, *Falco berigora* (Falconidae), was reported in Uluru National Park, Northern Territory, in central Australia, that was unsuccessful due to intervention of the observer (Fyfe 1981. Herpetofauna 13:31). Another Australian eagle, *Aquila audax*, was reported as a predator of the large, closely related lizard *Trachydosaurus rugosus asper* (Scincidae; regarded as congeneric with *Tiliqua* by some authors, e.g., Shea 1992, *op. cit.*) as well as an adult snake *Pseudonaja textilis* (Elapidae) in the Riverina region of New South Wales, eastern Australia (Metcalfe and Driver 2008. Herpetol. Rev. 39:229), and at the other end of the raptor prey size scale, there is a report of predation by *F. berigora* on the small skink *Carlia munda* in Western Australia (Metcalfe & Peterson 2005. Herp. Rev. 36(4):445). The above record is also notable as a possible case of lardering of prey by an Australian raptor; lardering of prey including lizards in Australia is usually associated with butcherbirds *Cracticus* spp. (Artamidae: Cracticinae) (e.g., on *Ctenotus regius*, Fitzsimons and Thomas 2010. Herpetol. Rev. 41:76–77).

PHOTO BY D. STOVANOVIC

FIG. 1. Dead *Tiliqua multifasciata*, prey item of Little Eagle (*Hieraaetus morphnoides*).

We thank Dejan Stovanovic for telephotography of the *T. multifasciata* on our behalf.

MAGNUS PETERSON, Unit 5/33 Point Walter Rd., Bicton, Western Australia, Australia 6157 (e-mail: magnuspeterson1955@yahoo.com.au); **DEAN C. METCALFE**, PO Box 4056, Werrington, New South Wales, Australia 2747 (e-mail: dean_metcalfe@yahoo.com.au).

***TROPIDOPHORUS BERDMOREI* (Berdmore's Water Skink). DIET.** Berdmore's Water Skink is known to be closely associated with water (Taylor 1963. Univ. Kansas Sci. Bull. 44:687–1077). It feeds principally on water insects, small crustaceans, and worms along the banks and under rocks in the stream bed (Cox et al. 1998. A Photographic Guide to Snakes and other Reptiles of Thailand and South-East Asia. Asia Book, Bangkok. 144 pp.). However, Das (2010. A Field Guide to the Reptiles of Southeast Asia. New Holland, London. 376 pp.) noted that the diet of *Tropidophorus*

berdmorei was unstudied. Here we report prey items of *T. berdmorei* from the Por-Por-Por Waterfall, Doi Suthep-Pui National Park, Muaeng District, Chiang Mai Province, northern Thailand.

An individual *T. berdmorei* was caught at 2030 h on 30 October 2013 in a hilly stream in evergreen forest (18.80642°N, 98.976694°E, WGS 84; 1140 m elev.). It was kept overnight in a plastic bag and a fecal pellet was collected from the bag the next morning. The pellet was composed of three discernable items, including an individual of *Jalysus* sp. (Berytidae: Hemiptera), an individual of a harvestman spider (Sclerosomatidae: Opiliones), and a section of a cricket leg belonging to the family Glylidae (Orthoptera). As information concerning the diet of *T. berdmorei* is presently poorly known, the results of the present work provide preliminary data on the diet of this skink and imply that further study is needed.

We thank Sasitorn Hasin for confirming prey items. Funding was provided by grants from the National Research Council of Thailand for PD and the Faculty of Science (Khon Kaen University) for YC. Lastly, we thank the Department of National Parks, Wildlife and Plants Conservation (DNP) for the permit.

YODCHAIY CHUAYNKERN (e-mail: yodchaiy@kku.ac.th) and **CHANTIP CHUAYNKERN**, Department of Biology, Faculty of Science, Khon Kaen University, Muaeng, Khon Kaen 40002, Thailand; **PRATEEP DUENGKAE**, **YUWADEE PONPITUK,** and **WATTANACHAI TASEN,** Department of Forest Biology, Faculty of Forestry, Kasetsart University, Jatujak, Bangkok 10900, Thailand.

***TROPIDURUS TORQUATUS*. MELANISM.** Melanism is the expression of darker skin color of an individual when compared to conspecifics because of an increase in epidermal pigments known as melanins (Kettlewell 1973. The Evolution of Melanism. Claredon Press, Oxford. 448 pp.). This characteristic may provide some advantages for ectotherms as dark coloration of the skin implies thermoregulatory (Clusella-Trullas et al. 2007. J. Therm. Biol. 32:235–245) and performance advantages (Castella et al. 2013. Ecology 90:2297–2312). Although melanism has been reported for several reptile species (e.g., Silva et al. 1999. J. Ven. Anim. Tox. 5:91–97; Pearse and Pogson 2000. Evol. 54:1041–1046), reports for melanism in a tropidurid lizards are, to our knowledge, unknown. Herein we provide the first record of melanism for the lizard *Tropidurus torquatus*, a heliophilous species widely distributed along open sites from South America.

FIG. 1. A) Dorsal and B) ventral views of melanistic *Tropidurus torquatus*.

Although a common feature in reptiles, expression of melanism in natural populations is infrequently observed (e.g., Jambrich and Jandzik 2012. Herpetol. Notes 5:219–221). Thus, our report of the first melanistic *T. torquatus* is noteworthy.

We thank ICMBio for the license number 25819-3; CABG and LBN thank FAPEMIG; LBN also thanks CNPq for the financial support; LKP thanks CAPES for the grant.

***UMA RUFOPUNCTATA* (Yuman Desert Fringe-toed Lizard). ENDOPARASITES.** *Uma rufopunctata* is restricted to southwestern Arizona and northwestern Sonora where it is associated with windblown sand deposits (Turner and Rorabaugh 2009. *In* Jones and Lovich [eds.], Lizards of the American Southwest: A Photographic Field Guide, pp. 274–277. Rio Nuevo Publishers, Tucson, Arizona). To our knowledge there are no published accounts of helminths for *U. rufopunctata*. In this note we establish the initial helminth list for *U. rufopunctata*.

A sample of 11 *Uma rufopunctata* (mean SVL = 71.87 ± 12.2 SD, range = 60–101 mm) collected 40 km E of San Luis (32.4841229°N, 114.7890582°W), Sonora, Mexico, May 1966 and deposited in the herpetology collection of the Natural History Museum of Los Angeles County (LACM), Los Angeles, California, USA as LACM 8946, 8952, 8962, 8963, 8968, 8969, 8976, 8977, 8985, 8997, 8998 was examined for helminths.

The digestive tract was removed, opened, and the esophagus, stomach, small and large intestines and their contents were examined under a dissecting microscope. Twelve cestodes were found in the small intestines of *U. rufopunctata*. They were regressively stained in hematoxylin, destained in acid alcohol, dehydrated in an ascending series of ethanol, mounted in balsam, on a glass slide, cover slipped, studied under a compound microscope, and identified as *Oochoristica macallisteri*. Prevalence = number infected/number examined × 100 = 33%; mean intensity (mean number of helminths per infected lizard = 2.4 ± 1.3, SD, range = 1–4). Two hundred-twelve nematodes were found in the stomachs of *U. rufopunctata*. Nematodes were cleared in a drop of lactophenol on a microscope slide, cover slipped, studied under a compound microscope and identified as *Skrjabinoptera phrynosoma* (prevalence = 100%; mean intensity = 20.1 ± 16.2 SD, range = 1–96). Voucher helminths were deposited in the United States National Parasite Collection (USNPC), Beltsville, Maryland, USA as *Oochoristica macallisteri* (USNPC 107267) and *Skrjapinoptera phrynosoma* (USNPC 107268).

Oochoristica macallisteri was described from *Uta stansburiana* from California (Bursey and Goldberg 1996. Folia Parasitol. 43:293–296) and was also found in *Hemidactylus turcicus* from Arizona (Goldberg et al. 2000. Herpetol. Rev. 31:240). *Oochoristica scelopori* has been reported from *Uma* congeners *U. notata* and *U. inornata* (Telford 1970. Am. Midl.

Nat. 83:516–554). The two species, *O. macallisteri* and *O. scelopori* differ in length, shape of strobila, and number of testes per proglottid: *O. macallisteri*, 25 mm in length, greatest width at posterior end, 12–20 proglottids; *O scelopori*, 120 mm in length, posterior half of body with equal width, 22–43 testes per proglottid. Because our specimens averaged 20 mm in length, greatest width at posterior end with continual narrowing toward scolex and less than 20 testes per proglottid, we have assigned them to *O. macallisteri*.

Skrjabinoptera phrynosoma was reported in the *Uma* congeners *U. inornata*, *U. notata*, and *U. scoparia* (Telford 1970, *op. cit.*) and is the most common helminth in members of the genus *Phrynosoma* (Goldberg and Bursey 1991. Southwest. Nat. 36:365–368; Goldberg et al. 1993. J. Helminthol. Soc. Washigton 60:234–238). A host list for *S. phrynosoma* is in Goldberg and Bursey (*op. cit.*). *Uma rufopunctata* represents new host records for *Oochoristica macallisteri* and *Skrjabinoptera phrynosoma*.

We thank G. Pauly (LACM) for permission to examine *U. rufopunctata*.

STEPHEN R. GOLDBERG, Natural History Museum of Los Angeles County, Section of Herpetology, Los Angeles, California 90007, USA (e-mail: sgoldberg@whittier.edu); **CHARLES R. BURSEY,** Pennsylvania State University, Department of Biology, Shenango Campus, Sharon, Pennsylvania, USA (e-mail: cxb13@psu.edu); **JEANETTE ARREOLA,** Whittier College, Department of Biology, Whittier, California 90608, USA (e-mail: jarreola@poets.edu).

***UROSTROPHUS VAUTIERI* (Brazilian Steppe Iguana). ENDOPARASITES.** *Urostrophus vautieri* is a lizard native to southern and southeastern regions of Brazil (Santos et al. 2009. Check List 5:533–536; Souza-Filho 2011. Check List 7:876–877). There are no reports of helminth parasites for *U. vautieri* prior to this study.

The intestine of one adult female *U. vautieri* (SVL = 592 mm) deposited in the Coleção de Répteis do Laboratório de Zoologia (CRLZ), Centro Univesitário de Lavras – UNILAVRAS, Minas Gerais, Brazil, as CRLZ 256, was examined. This specimen originates from Reserva Biológica Unilavras – Boqueirão (RBUB) (21.346°S, 44.990°W, datum WGS84; 1250 m elev.), municipality of Ingaí in riparian forest associated with Cerrado, state of Minas Gerais, Brazil, and was collected in November 2010. The intestine was examined for helminths using a stereomicroscope. For identification, nematodes were cleared in Amann's lactophenol (1:1:2:1 phenol: lactic acid: glycerine: water) on a microscope slide, and observed with light microscope. Nematodes were identified according to Anderson et al. (2009. Keys to the Nematode Parasites of Vertebrates. CAB International, Wallingford, UK. 463 pp.).

Eleven individuals of one unidentified species of *Strongyloides* (Rhabditida, Strongyloididae) were found. Voucher specimen was deposited in the Instituto Oswaldo Cruz Helminthological Collection (CHIOC), Rio de Janeiro, Brazil, as CHIOC 35898.

To date, the only species of *Strongyloides* reported parasitizing lizards of Brazil is *Strongyloides cruzi,* collected in the small intestine of *Hemidactylus mabouia* (a non-native species) from the municipality of Rio de Janeiro (Rodrigues 1968. Atas Soc. Biol. Rio de Janeiro 12:31–32; Vicente et al. 1993. Rev. Bras. Zool. 10:19–168; Ávila and Silva 2010. Journal of Venomous Animals and Toxins including Tropical Disease 16:543–572). The current report is a new host record for *Strongyloides* sp. in Brazilian lizards, and the first report of helminths in *Urostrophus vautieri*.

***VARANUS PANOPTES* (Yellow-spotted Monitor). DIET AND BEHAVIOR.** *Varanus panoptes* is a large terrestrial lizard that inhabits much of northern Australia (Christian 2004. *In* Pianka and King [eds.], Varanoid Lizards of the World, pp. 423-429. Indiana Univ. Press, Bloomington). The species is a generalist predator and will consume a wide range of invertebrates and small to medium-sized vertebrates (Shine 1986. Herpetologica 42:346–360). *Varanus panoptes* is a voracious predator and exploits some prey species to the extent that it can regulate prey populations and their recruitment success (Doody et al. 2006. Wildl. Res. 33:349–354; Doody et al. 2009. Anim. Conserv. 12:46–53). This species is highly seasonal, with declines in foraging activity during dry conditions between June and October attributed to a reduction in the availability of free standing water and prey items (Christian et al. 1995. Oecologica 103:349–357; Blamires 2004. Copeia 2004:370–377). Despite the clearly defined patterns of foraging activity in *V. panoptes*, some studies have found continued activity in individuals during the dry season in Northern Australia. For example, JSD (pers. obs.) observed a large male *V. panoptes* foraging for frogs in the late dry season along the Chamberlain River in the East Kimberley, Western Australia. Christian et al. (*op. cit.*) found that *V. panoptes* living on the floodplain during the early dry season remained active for longer than those living in woodland areas. A study by Blamires (*op. cit.*) also found that individual *V. panoptes* at Fog Bay in the Northern Territory would remain active during the dry season, but restricted that activity to habitats that were rich in prey. In northern Australia, the availability of *V. panoptes* prey items appears to be linked to seasonal changes including temperature and rainfall (Griffiths and Christian 1996. Aust. J. Ecol. 21:386–398). These factors, together with the variety of habitats used by *V. panoptes*, could potentially result in competing and as yet unknown factors that influence activity patterns at the local scale. By understanding the dietary preferences of individual *V. panoptes* during the dry season, we can understand why some individuals continue to remain active and what factors influence that activity. Here, we present two observations of active feeding by *V. panoptes* during the dry season and present an arboreal prey item that has not previously been recorded in the diet of the species. We also discuss the implications of this prey item for maintaining activity in these individuals during the dry season in northern Australia.

On 5 August 2013, an adult male *V. panoptes* (SVL 470 mm, total length 1020 mm) was trapped in a modified wire cage trap as part of a monitoring program in the Casuarina Coastal Reserve (12.360557°S, 130.871255°E). Following the release of the animal, a regurgitated food bolus comprising fur and bones was found in the trap. The bolus included a partially digested forefoot identified as being from a juvenile Northern Brush-tail Possum

(*Trichosurus vulpecula*). On 8 September 2013, a different male *V. panoptes* (SVL 395 mm, total length 996 mm) was trapped in a cage trap as part of the same monitoring program. As with the first observation, a regurgitated bolus comprising hair and bones was found in the trap. The second sample was also identified as *T. vulpecula* using the methods of Brunner et al. (2002. Hair ID, An Interactive Tool for Identifying Australian Mammalian Hair. CSIRO Publishing, Melbourne. CD-ROM) and Brunner and Conan (1974. Identification of Mammalian Hair. Inkata Press, Melbourne. 176 pp.). Daily checking of the traps and footage from remote cameras (Moultrie® D-40) confirmed that the food items were regurgitated by the trapped animals. Unfortunately, the state of both samples meant that it was not possible to confirm whether the two observations reflect prey capture or scavenging.

Although previous studies have found other smaller nocturnal and arboreal mammals in the diet of *V. panoptes* (see Shine et al., *op. cit.*), our observations are the first record of *T. vulpecula* in the diet of this species. In addition, our observations provide further evidence of active foraging in *V. panoptes* when conspecifics are generally inactive. In the absence of further diet and movement information, we can only speculate on the factors that are responsible for maintaining activity in *V. panoptes*. Based on the results of previous studies, it is possible that the successful exploitation of certain food items allow individuals to continue foraging through the dry season. These observations are the first to confirm that *T. vulpecula* is included in the diet of *V. panoptes* during the dry season. Further studies should be undertaken to confirm whether *V. panoptes* is an active predator of *T. vulpecula* as well as quantifying the importance of this and other dietary items during the dry season along the coastal reserves in the northern Australia.

SQUAMATA — SNAKES

***COLUBER* (= *MASTICOPHIS*) *FLAGELLUM* (Coachwhip). DIET / OPHIOPHAGY.** *Coluber flagellum* is known to take a variety of prey items, including snakes (Beaman and Basey 2011. Herpetol. Rev. 42:437). Tabor and Germano (1997. Herpetol. Rev. 28:90) reported a decomposing *Crotalus oreganus oreganus* (Northern Pacific Rattlesnake) in the esophagus of a road-killed *C. flagellum*, but it was not known whether the snake had been taken alive or eaten as carrion. Here we report a *C. oreganus helleri* (Southern Pacific Rattlesnake) as a prey item for *C. flagellum*.

On 25 June 2013, we encountered a *C. flagellum* ingesting a live *C. oreganus helleri* (SVL ca. 40 cm) near San Timoteo Creek, west of Beaumont, Riverside Co., California, USA (33.945918°N, 117.056755°W; datum WGS84). The head and neck of the rattlesnake were in the mouth of the Coachwhip, which had looped its body across the rattlesnake, pinning it to the ground (Fig. 1). As we approached to photograph the snakes, the coachwhip was startled and released the rattlesnake. The stunned rattlesnake thrashed about for a few minutes before resuming its normal behavior. The snakes were photographed and digital images were deposited in the Natural History Museum of Los Angeles County (LACM PC 1674–1675).

FIG. 1. *Coluber flagellum* feeding on *Crotalus oreganus helleri*, near Beaumont, California, USA.

STEPHEN J. MYERS, AMEC Environment and Infrastructure, 3120 Chicago Avenue, Suite 110, Riverside, California 90507, USA (e-mail: stephen-myers@earthlink.net); **VESTA A. MYERS**, 15598 Turnberry Street, Moreno Valley, California 92555, USA.

***COLUBER* (= *MASTICOPHIS*) *FLAGELLUM* (Coachwhip). BEHAVIOR / NOCTURNAL ACTIVITY.** *Coluber flagellum* is a large, slender-bodied colubrine snake that ranges widely across portions of the southern United States and northern Mexico (Ernst and Ernst 2003. Snakes of the United States and Canada. Smithsonian Institute Press, Washington, D.C. 668 pp.). *Coluber flagellum* is generally considered a strictly diurnal species that maintains a high and narrow temperature profile by alternating between bouts of active foraging and subterranean inactivity (Secor and Nagy 1994. Ecology 75:1600–1614). Radio-telemetry studies of *C. flagellum* in Florida indicated that no movement occurred at night, save for shifts within burrows (Dodd and Barichivich 2007. Florida Sci. 70:83–94). In addition and despite a number of studies involving this species, accounts pertaining to neonatal activity are lacking. Here, we describe a nocturnal encounter with multiple neonate *C. flagellum*.

At 0033 h on 13 July 2013, we encountered two neonate (1 , 1) *C. flagellum* while driving on Highway 6, approximately 25 km W of Los Lunas (Valencia Co.), New Mexico, USA (34.84474°N, 107.05367°W, datum WGS 84; elev. 1602 m). The first individual was spotted from our vehicle; after pulling over and searching the area, a second neonate was discovered a few meters away. The postures of both snakes indicated they were in the process of crossing the road from the west (i.e., their bodies were straight and angled perpendicular to the road). We did not collect morphometric data from either snake, but based on photographs we estimate that each had a total body length of ca. 25–35 cm, which according to Ernst and Ernst (*op. cit.*) would qualify these individuals as hatchlings. A recent hatching and dispersal event, possibly cued by rain earlier in the day, might provide an explanation as to why these snakes were moving in such close proximity to each other and at such an unusual time of day for the species. The only other hint of nocturnal activity in this species was reported by Medica (2011. Herpetol. Rev. 42:612–613), who inferred that a *C. f. piceus* found basking in a creosote bush at 0610 h had spent the night there. We have

unambiguously documented a rare instance of nocturnal activity in *C. flagellum*.

IWO P. GROSS, Department of Biological and Environmental Sciences, Alabama A & M University, Huntsville, Alabama 35810, USA (e-mail: iwogross@gmail.com); **MEAGAN A. THOMAS**, **CYNTHIA M. CARTER**, Department of Biological Sciences, Eastern Illinois University, Charleston, Illinois, 61920, USA; **ANDREW M. DURSO**, Department of Biology, Utah State University, Logan, Utah 84321, USA.

***CONOPSIS LINEATA* (Lined Tolucan Ground Snake). DIET.** *Conopsis lineata* is distributed in central and southern Mexico, from 1750 to 3100 m elev., in a variety of habitats (Goyenechea and Flores-Villela 2006. Zootaxa 1271:1–27; Goyenechea 2009. Rev. Mex. Biodiv. 80:721–725). Its diet has been reported to consist of insects, such as grasshoppers and termites (Canseco-Márquez and Gutiérrez-Mayén. 2010. Anfibios y Reptiles del Valle de Tehuacán–Cuicatlán. Comisión Nacional para el Conocimiento y Uso de la Biodiversidad, México, D.F. 302 pp.), but there is no detailed information on the species consumed.

On 27 June 2010, at 1537 h, a *C. lineata* (total length = 245 mm) was found under a rock in oak forest (*Quercus* sp.) on Sierra de Lobos, Municipality of San Felipe, Guanajuato, México (21.328292°N, 101.616183°W, datum WGS84; elev. 2627 m). Following capture, the snake was palpated and regurgitated a partially digested spider, which was identified as a member of the genus *Zorocrates* (Araneae, Zorocratidae), which are common in the area. This is the first record of a *Zorocrates* spider in the diet of *C. lineata*. The snake and the spider were deposited in the Herpetological Collection, Universidad Autónoma de Aguascalientes (CV-0327).

CHRISTIAN MARTIN GARCÍA-BALDERAS, El Colegio de la Frontera Sur, Unidad Chetumal, CP 77014, Chetumal, Quintana Roo, México (e-mail: chrisgarbal@gmail.com); **GUSTAVO ERNESTO QUINTERO-DÍAZ,** Universidad Autónoma de Aguascalientes, Centro de Ciencias Básicas, Departamento de Biología, C.P. 20131, Aguascalientes, Ags, México; **CESAR RAZIEL LUCIO-PALACIO**, Pronatura Veracruz A.C. Sección Ecoforestal, Xalapa, Veracruz, México; **DANIELA VALDEZ-JIMÉNEZ,** Universidad Autónoma de Aguascalientes, Ciudad Universitaria, C.P. 20131 Aguascalientes, Ags, México.

***DENDRELAPHIS CYANOCHLORIS* (Wall's Bronzeback). ENDOPARASITE.** *Dendrelaphis cyanochloris* occurs in Myanmar, Peninsular Thailand, Laos and Peninsular Malaysia, Bangladesh, and north-eastern India (Das 2010. A Field Guide to the Reptiles of South-East Asia. Myanmar, Thailand, Laos, Cambodia, Vietnam, Peninsular Malaysia, Singapore, Sumatra, Borneo, Java, Bali. New Holland Publishers, London. 376 pp.). One female *D. cyanochloris* (SVL = 803 mm) was collected 2 July 2005 in West Malaysia, Pahang State, Pulau Tioman (2.8167°N, 104.1833°E; datum WGS84) by LLG and deposited in the herpetology collection of La Sierra University (LSUHC 7306), Riverside, California, USA. We know of no published reports of helminths from *D. cyanochloris*.

The body cavity was opened and the coelomic cavity was searched for helminths. One whitish helminth ca.1 × 2 mm was found embedded in coelomic fat. It was identified as a larval tapeworm (cestode cysticercoid), characterized by a fully withdrawn scolex and solid unsegmented body (Bush et al. 2001. Parasitism, The Diversity and Ecology of Animal Parasites. Cambridge University Press, Cambridge, UK. 566 pp.). The cysticercoid was deposited in the United States National Parasite Collection (USNPC), Beltsville, Maryland, USA, as USNPC 107219. Development to the adult tapeworm would have occurred when the *D. cyanochloris* was eaten by a final (definitive) host, thus this snake was most likely a paratenic (= transport) host. *Dendrelaphis cyanochloris* represents a new host record for cestode cysticercoids .

STEPHEN R. GOLDBERG, Whittier College, Department of Biology, Whittier, California 90608, USA (e-mail: sgoldberg@whittier.edu); **CHARLES R. BURSEY,** Pennsylvania State University, Shenango Campus, Department of Biology, Sharon, Pennsylvania 16146, USA (e-mail: cxb13@psu.edu); **L. LEE GRISMER,** La Sierra University, Department of Biology, Riverside, California 92515, USA (e-mail: lgrismer@lasierra.edu).

***DENDRELAPHIS CYANOCHLORIS* (Wall's Bronzeback). REPRODUCTION.** *Dendrelaphis cyanochloris* occurs in Myanmar, Peninsular Thailand, Laos and Peninsular Malaysia, Bangladesh, and north-eastern India (Das 2010. A Field Guide to the Reptiles of South-East Asia, Myanmar, Thailand, Laos, Cambodia, Vietnam, Peninsular Malaysia, Singapore, Sumatra, Borneo, Java, Bali. New Holland Publishers, London. 376 pp.). There is a report of *D. cyanochloris* having clutches of 3–5 eggs in Das (*op. cit*). The purpose of this note is to add information on the reproductive biology of *D. cyanochloris* from a histological examination of gonadal material.

A sample of 10 *D. cyanochloris* from Peninsular Malaysia consisting of four males (mean SVL = 586.8 mm ± 57.9 SD, range = 523–663 mm) and six females (mean SVL = 745.5 mm ± 42.8 SD, range = 707–803 mm) deposited in the herpetology collection of La Sierra University (LSUHC), Riverside, California, USA, were examined (by state): Pahang, LSUHC 4493, 4611, 5409, 5416, 6431, 7306, 7307 and Pinang, LSUHC 6768, 6769, 6771. Snakes were collected between 2002 and 2005. The left testis was removed from males and the left ovary was removed from females. Enlarged follicles (> 7 mm diameter) or oviductal eggs were counted. Histology slides were deposited at LSUHC.

The only stage noted in the testicular cycle was spermiogenesis in which the lumina of the seminiferous tubules were lined by sperm or groups of metamorphosing spermatids. Monthly distribution of males was March (N = 1), July (N = 2), August (N = 1). The presence of spermiogenic males in widely separated months (March and August), suggests *D. cyanochloris* has an extended reproductive cycle. The smallest reproductively active male (spermiogenesis) measured 523 mm SVL (LSUHC 4611) and was collected in July.

Three stages were noted in the ovarian cycle of *D. cyanochloris*: 1) quiescent, no yolk deposition; 2) enlarged follicles > 7 mm diameter; 3) oviductal eggs. Four July females, consisted of two with quiescent ovaries, one with four enlarged follicles (> 7 mm and one with seven oviductal eggs. Two August females consisted of one with quiescent ovaries and one with four enlarged follicles (> 7 mm). Mean clutch size for three females was 5.0 ± 1.7 SD, range = 4–7. The smallest reproductively active female (follicles > 7 mm diameter) measured 707 mm SVL (LSUHC 6431) and was collected in July. There was no suggestion (oviductal eggs and concurrent yolk deposition in the same female) to suggest *D. cyanochloris* females produce multiple clutches. Seven is a new maximum clutch for *D. cyanochloris*.

STEPHEN R. GOLDBERG, Whittier College, Department of Biology, Whittier, California 90608, USA (e-mail: sgoldberg@whittier.edu); **L. LEE GRISMER,** La Sierra University, Department of Biology, Riverside, California 92515, USA (e-mail: lgrismer@lasierra.edu).

***EUNECTES MURINUS* (Green Anaconda). BEHAVIOR / SIDEWINDING.** Sidewinding is a form of locomotion unique to snakes. Unlike lateral undulation and rectilinear locomotion,

which rely on static friction, sidewinding allows a snake to move across very loose or smooth terrain efficiently (Gans 1962. Am. Zool. 2:167–182). Unlike other modes of locomotion, in sidewinding the direction of movement is perpendicular to the long axis of the body, resulting in tracks that run oblique to the direction of movement. Sidewinding is also the only mode of locomotion in snakes where there is no sliding point of contact with the substrate. The portions of the body that are moving are lifted above the substrate (Gans 1974. Biomechanics: An Approach to Vertebrate Biology. Lippincott, Philadelphia. 261 pp.). No study to date has described sidewinding in a large bodied constrictor. Here we note the first evidence of sidewinding in a 2.75-m *Eunectes murinus;* this is currently the largest snake ever observed sidewinding in the natural environment.

On 5 June 2011, an ecotourism group in the vicinity of Infierno, Peru, discovered an *E. murinus* and moved the snake onto a small area of grass for photographing. While on the grass, the *E. murinus* was videotaped. After a few strike attempts directed at one of the group members, the snake attempted to escape, transitioning into a rapid sidewinding motion to flee. One member of the group retrieved the snake, returning it the center of the grassy clearing, and it once again attempted to flee via sidewinding. Images taken from the video clearly show the anaconda lifting sections of its body off the substrate as it moves along the ground, while the points on the substrate remain static (Fig. 1). Unlike similar modes of locomotion (e.g., "mud-jumping," Bustard 1969. Herpetologica 25:164–170), the sections of the body elevated are between contact points and are not restricted to the anterior or posterior regions. Elevated regions of the body travel approximately 1 m before returning to the substrate. The movement is perpendicular to the long axis of the body, and the traveling wave moving down the length of the snake occurs at the same speed as forward progression.

FIG. 1. Two still images showing the key aspects of sidewinding behavior in an *Eunectes murinus*. Sections of the body are looped and lifted off the substrate as the snake moves.

Sidewinding is most commonly observed in species moving on loose or smooth terrain, and has been considered an adaptation to these environments (Secor et al. 1992. J. Exp. Biol. 163:1–14). However, the anaconda in our video is moving on a grassy substrate, suggesting that sidewinding may be more widespread in snakes than previously considered, and that this behavior might not be restricted to loose or smooth terrain. An alternative hypothesis, that sidewinding evolved as a rapid escape behavior in open habitat (Cowles 1956. Copeia 1956:211–214), is supported by this observation.

WILLIAM G. RYERSON (e-mail: william.ryerson@uconn.edu) and **SARA HORWITZ**, Department of Ecology and Evolutionary Biology, University of Connecticut, 75 North Eagleville Road, Storrs, Connecticut 06269, USA.

***HYPSIGLENA JANI* (Chihuahuan Nightsnake). DIET.** The diet of *Hypsiglena jani* primarily includes lizards and small snakes, although lizard eggs, frogs, insects, and worms are occasionally consumed (Werler and Dixon 2000. Texas Snakes: Identification, Distribution, and Natural History. Univ. Texas Press, Austin. xv + 437 pp.; Ernst and Ernst 2003. Snakes of the United States and Canada. Smithson. Inst. Press, Washington, D.C. 668 pp.). On 5 September 2013, at 2110 h, an adult female *H. jani* (SVL = 290 mm; tail length = 56 mm; 21.1 g [with ingested prey]) was discovered subduing and eating an adult *Hemidactylus turcicus* (Mediterranean Gecko) (Fig. 1) in the backyard of VMS's home, located in El Paso, El Paso Co., Texas, USA (30.4635°N, 105.0055°W, datum WGS84; elev. 1215 m). After ca. 25 min the snake released the dead gecko and initially swallowed the detached tail that had been lost as a result of resistance by the lizard after being attacked. Next the gecko's body was consumed headfirst, a process that lasted about 20 min. *Hemidactylus turcicus* is an exotic species that is firmly established in El Paso and many other locations in the southern U.S. However, this is the first record of this species in the diet of *H. jani.*

FIG. 1. Adult *Hypsiglena jani* consuming an adult *Hemidactylus turcicus* in El Paso, El Paso Co., Texas, USA.

VICENTE MATA-SILVA (e-mail: vmata@utep.edu) and **JERRY D. JOHNSON** (e-mail: jjohnson@utepe.du), Department of Biological Sciences, University of Texas at El Paso, El Paso, Texas 79968, USA; **LARRY DAVID WILSON**, 16010 S. W. 207th Avenue, Miami, Florida 33187, USA, and Centro Zamorano de Biodiversidad, Escuela Agrícola Panamericana Zamorano, Depto. Francisco Morazán, Honduras (e-mail: bufodoc@aol.com).

***LEPTOPHIS AHAETULLA* (Parrot Snake). DIET.** *Leptophis ahaetulla* is widespread in Central and South America (Oliver 1948. Bull. Am. Mus. Nat. Hist. 92:157–280). Reported diet of *L. ahaetulla* consists mostly of frogs, but lizards and birds have also been recorded (Teixeira and Port 1991. Herpetol. Rev. 22:132; Albuquerque et al. 2007. J. Nat Hist. 41:1237–1243). On 12 April 2011, at ca. 0900 h, during an ornithological expedition to the woods surrounding the Barreira do Inferno military facility, near the city of Natal, Rio Grande do Norte, Brazil (55.5°S, 10.35°W, datum WGS84; elev. 25 m), we observed an adult *L. ahaetulla* (total length ca. 80 cm) among the branches of a shrub preying on a juvenile *Turdus leucomelas* (Pale-breasted Thrush; Fig. 1). This is the first record of *T. leucomelas* in the diet of *L. ahaetulla*.

This study was supported by research grants from the Brazilian National Council for Scientific and Technological Development (CNPq) to MMR (No. 372998/2010-0) and EMXF (No. 309424/2011-9).

FIG. 1. *Leptophis ahaetulla* preying on a juvenile *Turdus leucomelas* in the coastal region near Natal, Rio Grande do Norte, Brazil.

***LIOTYPHLOPS ALBIROSTRIS* (White-nosed Blindsnake). PREDATION.** *Liotyphlops albirostris* is a medium-sized (to 223 mm) blindsnake occurring in Panama, Colombia, Venezuela, and Ecuador. This species is considered rare and little is known about its ecology or biology (Savage 2002. The Amphibians and Reptiles of Costa Rica: A Herpetofauna between Two Continents, between Two Seas. Univ. Chicago Press, Chicago, Illinois. 934 pp.). An adult (snout–urostyle length = 107.6 mm, head width = 42.6 mm) female *Rhinella marina* (Cane Toad) was collected from beneath a house in suburban Clayton, Republic of Panama (9.001667°N, 79.576944°W; datum WGS 84) at 2100 h on 5 September 2013, and retained in a moist cloth bag overnight. The following morning a deceased but intact blind snake (total length = 124 mm) was discovered protruding headfirst from the toad's cloaca (Fig. 1). The snake was preserved in 70% ethanol and identified as *L. albirostris* via examination of its facial scales beneath a dissecting scope (verified by Sean Graham and Roberto Ibáñez).

FIG. 1. *Liotyphlops albirostris* (White-nosed Blind Snake) protruding from the cloaca of a female *Rhinella marina* (Cane Toad) collected in the Republic of Panama.

Interestingly, the specimen was completely undigested. A live *Ramphotyphlops braminus* (Brahminy Blindsnake) was similarly recovered from the cloaca of a *Duttaphrynus melanostictus* (Common Asian toad) in East Timor (O'Shea et al. 2013. Herpetol. Notes 6:467–470). Blindsnakes (*R. braminus*, *R. guentheri*, and *R. unguirostris*) have also been recorded in the diet of *R. marina* (10 of > 3000 toads) in their invasive range in Australia (Pizzatto et al. 2012. Herpetol. Rev. 43:469–471); and blindsnakes of the genus *Typhlops* were discovered in the gut contents of 19 of ~5000 Cane Toads in their invasive range in the Philippines (Rabor 1952. Copeia 1952:281–282). As with the majority of the Australian records (Pizzatto et al. 2012, *op. cit.*), this blindsnake was consumed in the wet season when blindsnakes may be more surface-active due to flooding of fossorial habitat.

I thank Mark Torchin for assistance in capturing the wily toad. My research was supported by an A. Stanley Rand Fellowship.

CRYSTAL KELEHEAR, Smithsonian Tropical Research Institute, Apartado 0843-03092, Balboa, Ancon, Republic of Panama; e-mail: crystal.kelehear@hotmail.com.

***MICRUROIDES EURYXANTHUS* (Sonoran Coralsnake). DIET.** On 15 September 2012, 1848 h MST, we captured an adult *Micruroides euryxanthus* (photo voucher UAZ 57568-PSV; ca. 420 mm SVL) on Forest Road 39, Coronado National Forest, Santa Cruz Co., Arizona, USA (31.400899°N, 111.144186°W, datum NAD83; 1423 m elev.). The snake was maintained overnight and in the morning we found that it had regurgitated an adult female *Plestiodon callicephalus* (Mountain Skink) (UAZ 57462; 63 mm SVL, 58 mm tail). We released the snake on 16 September at the site of capture. Judging from its limb orientation, the skink had been ingested head-first and we discovered two puncture marks (3.62 mm apart) on the tail ventro-laterally, 24 mm posterior to the vent, suggesting that the animal had initially been caught by the tail.

This is the first report of *P. callicephalus* in the diet of *M. euryxanthus*. *Micruroides* are typically ophiophagus (Vitt and Hulse 1973. Herpetologica 29:302–304; Lowe et al. 1986. The Venomous Reptiles of Arizona. Arizona Game and Fish Dept.,

Phoenix. 115 pp.; G. R. Harper, pers. comm.). Although Lowe et al. (*op. cit.*) reported results from "field observations and laboratory experiments on foods and feeding" that "lizards taken" as *Micruroides* prey included skinks whose "young…have blue tails" (which could include *P. callicephalus* or *P. obsoletus*), they did not identify species of skink(s) or identify whether skinks had been fed to coralsnakes or found as natural prey items.

THOMAS R. JONES, Nongame Branch, Arizona Game and Fish Department, 5000 W. Carefree Highway, Phoenix, Arizona 85086, USA (e-mail: tjones@azgfd.gov); **KEVIN KRAHN**, Department of Applied Sciences and Mathematics, Arizona State University Polytechnic, Mesa, Arizona 85212, USA.

***MICRURUS SURINAMENSIS* (Aquatic Coralsnake). BEHAVIOR.** Coralsnakes (*Micrurus* spp.) are primarily fossorial and secretive, but arboreal behavior has been reported in *M. circinalis* (Sajdak 2000. Herpetol. Rev. 31:105), *M. fulvius* (Carr 1994. Naturalist in Florida: the Celebration of Eden. Yale Univ. Press, New Haven, Connecticut. 306 pp.), and *M. nigrocinctus* (Schmidt and Schmidt 1943. Field Mus. Nat Hist. Publ. Zool. Ser 12:129–134). *Micrurus surinamensis* is known to have aquatic habits and feeds mainly on fish and eels (Roze 1996. Coral Snakes of the Americas: Biology, Identification, and Venoms. Krieger Publ. Co., Malabar, Florida. 328 pp.). On 13 May 2013, at 1438 h (32°C), during an active search for amphibians and reptiles in the municipality of Cacoal, State of Rondônia, Brazil (11.488094°S, 61.438953°W; datum SAD69), we observed a juvenile male *M. surinamensis* (SVL = 400 mm) climbing on vegetation 2.38 m high within an open rainforest. This appears to be the first record of arboreality in *M. surinamensis*.

PEDRO HENRIQUE BERTÃO DÁVILA (e-mail: micrurus.snake@gmail.com), **HIDEKI SADADI TAKAHASHI,** and **MIGUEL HEYD OSHIRO BARBOSA,** Departamento de Zoologia, CEP: 76.963-665CP231, Facimed, Cacoal, Rondônia, Brazil.

***NERODIA SIPEDON PLEURALIS* (Midland Watersnake). ALBINISM.** Although there are several reports of albinism in *Nerodia sipedon sipedon* (Baker et al. [ed.] 1959. Publ. Mus. Michigan St. Univ. Biol. Ser. 1:133–159; Dyrkacz 1981. SSAR Herpetol. Circ. 11:1–31) we are not aware of any published account documenting albinism in *Nerodia sipedon pleuralis*. An unsexed *N. s. pleuralis* (SVL = 425 mm, Arkansas State University, Herpetological Museum; photo voucher ASUMZ 32763) was collected near Jasper, Newton Co., Arkansas, USA, in June 2012. It was donated to the Arkansas Game and Fish Commission Fred Berry Conservation Education Center (CEC), where it remains for viewing. The specimen is a true albino (Fig. 1). Interestingly, there was another albino specimen of *N. s. pleuralis* collected with the above but its disposition is unknown.

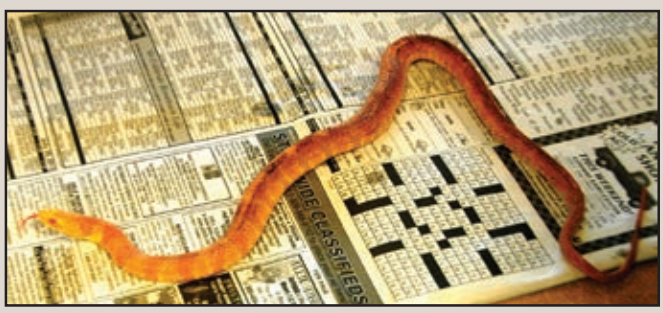

FIG. 1. Albino *Nerodia sipedon pleuralis* from Newton County, Arkansas.

We thank M. Doran, Facility Manager for the Fred Berry CEC, for information on this albino snake.

CHRIS T. McALLISTER, Science and Mathematics Division, Eastern Oklahoma State College, Idabel, Oklahoma 74745, USA (e-mail: cmcallister@se.edu); **HENRY W. ROBISON**, Department of Biology, Southern Arkansas University, Magnolia, Arkansas 71754, USA.

***OXYURANUS SCUTELLATUS* (Taipan). HOMING.** Very little is known about the daily behavior of *Oxyuranus scutellatus* under natural conditions (Shine and Covacevich 1983. J. Herpetol. 17:60–69). A serendipitous observation recorded at Wetherby Station (a cattle-raising property popular with eco-tourists, approximately 20 km SW of Port Douglas (16.645368°S, 145.354280°E, datum WGS84; elev. 399 m, 12 Sep 2012) in North Queensland, Australia, suggests homing and burrow re-use in this species.

We arrived at Wetherby Station about 1800 h and were directed to viewing stands on a concrete platform erected for cattle auction attendees. Our horse-mounted host allowed about 12 cattle to enter the viewing pen. When his previously-calm horse became agitated, our host looked into the area between viewing paddock and tree line, approximately 12 m distant, and exclaimed "Taipan." The snake was moving slowly but steadily—seemingly purposeful, head raised only slightly in the direction of the platform. Upon reaching the platform it turned without hesitation and crawled along the ground against the concrete edge of the platform in my direction. Stopping about 0.2 m from my foot, it reoriented and, seamlessly, crawled onto the concrete platform, passed beneath the viewing stand, and entered what was likely a rodent burrow located along the foundation for a barn just behind the viewing stand. Once in the burrow, the ~1.5-m Taipan re-emerged slightly, re-positioned and withdrew, leaving its head facing out from the burrow's entrance (Fig. 1). As this individual passed rapidly, but unhurriedly, through a small herd of cattle to take shelter in a burrow without apparent searching, this observation suggests it was returning to a previous refuge site, thereby demonstrating homing ability.

FIG. 1. *Oxyuranus scutellatus* (Taipan) settled in a burrow following the homing event.

STEPHEN D. BUSACK, North Carolina State Museum of Natural Sciences, 11 West Jones Street, Raleigh, North Carolina 27601-1029, USA (e-mail: sbusack348@aol.com).

***PARIAS SUMATRANUS* (Sumatran Pit Viper). DIET.** *Parias sumatranus* is a large (to 1355 mm total length) arboreal crotaline viper from the Greater Sundas (southern Thailand, Peninsular

FIG. 1. Euthanized specimen of *Parias sumatranus* (UNIMAS P0849) and its stomach contents, a *Maxomys baeodon* (UNIMAS P0872).

Malaysia, Sumatra, and Borneo) region of Southeast Asia. Its diet is poorly known, and reported to comprise small mammals, birds, and frogs (Stuebing and Inger 1999. A Field Guide to the Snakes of Borneo. Natural History Publications [Borneo], Kota Kinabalu. v + 235 pp.; Das 2010. A Field Guide to the Reptiles of South-east Asia. New Holland Publishers [UK], Ltd., London. 376 pp.), with no specific information.

On 10 July 2013, at ca. 1100 h, an adult female *Parias sumatranus* (Fig. 1; UNIMAS P0849; SVL = 887 mm; tail length = 28.4 mm; 252 g) was collected up the ridge from Sungei Sembu towards Sembu Waterfall, near the base (01.134556°N, 110.249444°E, datum Timbalai 1948; elev. ca. 250 m) of Gunung Penrissen, Sarawak, East Malaysia (Borneo). It was initially encountered at ca. 1.2 m above the ground on a low tree trunk within a riparian forest. The specimen was returned to the laboratory and euthanized; examination of the stomach contents revealed a recently-ingested rodent, *Maxomys baeodon* (UNIMAS P0872; 128 mm in head body length; 134 mm tail length; 68 g). This Bornean endemic has been reported from a few isolated localities between 900–1400 m elev. in Sabah and Sarawak (Heaney et al. 2008. *In* IUCN 2013. IUCN Red List of Threatened Species. Version 2013.1), and also at least two lowland localities: Sandakan Bay, Sabah (Payne et al. 1985. A Field Guide to the Mammals of Borneo. Sabah Society and World Wildlife Fund, Kota Kinabalu. 332 pp.), and at Planted Forest Zone, Bintulu Division, Sarawak (Ragai and Tuen 2007. *In* Stuebing et al. [eds.], Proc. Regional Conf. Biodiv. Conserv. Trop. Planted Forests SE Asia. pp. 164–168. Sarawak Forest Department, Sarawak Forestry Corporation and Grand Perfect Sdn Bhd., Kuching). It was swallowed head-first, and was estimated to be 26.98% of the body weight of the snake.

We thank the Institute of Biodiversity and Environmental Conservation, Universiti Malaysia Sarawak for supporting our research, and the Sarawak Forest Department for the issuance of a research permit (No. NCCD.907.4.4.[Jld.7]-38). Fieldwork at Gunung Penrissen was supported by a Shell Chair grant, SRC/05/2010(01).

INDRANEIL DAS (e-mail: idas@ibec.unimas.my), **PUI YONG MIN** (e-mail: pui8783ibec@gmail.com), **JONGKAR GRINANG** (e-mail: jgrinang@ibec.unimas.my), and **ANDREW ALEK TUEN** (e-mail: aatuen@ibec.unimas.my), Institute of Biodiversity and Environmental Conservation, Universiti Malaysia Sarawak, 94300 Kota Samarahan, Sarawak, Malaysia.

***PELAMIS PLATURA* (Yellow-bellied Seasnake). SHEDDING BEHAVIOR.** Shedding events of *Pelamis platura* have been reported as taking place always in water, either in the sea (Pickwell 1971. Copeia 1971:348–350; Voris 1983. *In* Janzen [ed.], Costa Rican Natural History, pp. 411–412. Univ. Chicago Press, Chicago, Illinois), or as captive individuals (Pickwell, *op. cit.*). Shedding is usually facilitated by the ability of these individuals to knot themselves, creating loops and coils, culminating with inverted and intact shed skins (Pickwell, *op. cit.*). Herein, we report an observation of shedding behavior of *P. platura* on sandy substrate out of the water.

FIG. 1. Male *Pelamis platura* shedding on a sandy beach in Rancho El Neptuno, Santa María Colotepec, Oaxaca, México.

At 1835 h on 7 April 2013 an adult male *P. platura* (Fig. 1) was observed shedding on a sandy beach at Rancho El Neptuno (15.792086°N, 96.959717°W; datum WGS 84) located in the municipality of Santa María Colotepec, Oaxaca, Mexico. The snake came out of the water and started to undulate its body to cause friction against the sand. Once the snake had shed most of the skin, it moved back towards the water and continued to rid itself of the last portion of skin every time it came in contact with the waves; knotting behavior was never displayed. The shedding episode lasted ca. 35 min. Pickwell (*op. cit.*) suggested that the knotting behavior of *P. platura* in aquatic environments evolved not just as a substitute for contact with solid substrate as an aid in shedding, but also for ridding themselves of ectoparasites and possibly freeing themselves from predators. To the best of our knowledge this instance represents the first reported observation of *P. platura* shedding behavior outside aquatic environments.

We thank J. M. Savage, who kindly provided information regarding this subject, and A. Rocha for his important comments on this note.

DANIELA SIGÜENZA-PÉREZ (e-mail: sigkaiser@hotmail.com), **JESÚS GARCÍA-GRAJALES**, Instituto de Recursos, Universidad del Mar, Campus Puerto Escondido, Oaxaca, México; **VICENTE MATA-SILVA**, Department of Biological Sciences, The University of Texas at El Paso, El Paso, Texas 79968, USA.

***PITUOPHIS CATENIFER SAYI* (Bullsnake). DIET.** *Pituophis catenifer sayi* is a wide-ranging subspecies that inhabits the sandy plains and prairies across the central two-thirds of Texas (Dixon 2013. Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 447 pp.). Most of its diet in the Great Plains region consists of small mammals (70%), bird eggs (20%), and birds (8%) (Rodríguez-Robles 2002. Biol. J. Linn. Soc. 77:165–183). Herein I describe *P. c. sayi* consuming a previously unknown prey species, *Carpodacus mexicanus* (House Finch).

On 29 May 2011, I collected a *P. c. sayi* (total length ca. 65 cm) inside the city limits of Lubbock, Lubbock Co., Texas, USA. The snake was placed in a container and while being transported

it regurgitated a single *C. mexicanus*. The finch was preyed on recently based on the amount of decomposition; the length of the tail and flight feathers indicated that it was most likely an adult. The area where the Bullsnake was collected is an older residential part of the city with large trees where House Finches and House Sparrows (*Passer domesticus*) are the most numerous small bird species. This account is the first known predation of *C. mexicanus* by *P. catenifer* and the first species from the family Fringillidae (Rodríguez-Robles, *op. cit.*), although the literature summary by Badyaev et al. (2012. *In* A. Poole [ed.], The Birds of North America Online. Cornell Lab of Ornithology, Ithaca, New York; http://bna.birds.cornell.edu/bna/species/046, accessed 17 May 2014) stated that nest predators of House Finches from British Columbia probably included Gopher Snakes.

STEPHEN KASPER, Lake Alan Henry Wildlife Mitigation Area, Parks and Recreation Department, City of Lubbock, Lubbock, Texas 79401, USA; e-mail: skasper@mail.ci.lubbock.tx.us.

***PITUOPHIS CATENIFER SAYI* (Bullsnake). ARBOREALITY.** Although generally considered to be primarily terrestrial and fossorial, *Pituophis catenifer* are on occasion known to climb into bushes and trees (Ernst and Ernst 2003. Snakes of the United States and Canada. Smithsonian Inst. Press, Washington, D.C. 668 pp.). In fact, there are several obscure records of members of *Pituophis* hunting for and/or feeding on birds arboreally (Rodríguez-Robles 2002. Biol. J. Linn. Soc. 77:165–183). For example, *P. catenifer* has been found preying on birds in their nests in a hawthorn tree in Washington State (3 m; Marr 1985. Murrelet 66:95–97), a cypress tree in California (2.6 m; Ervin and Rose 1973. Auk 90:682–683), a live oak tree in California (1.8 m; Cunningham 1955. Herpetologica 11:217–220), and an unknown tree in California (ca. 12 m; Eichholz and Koenig 1992. Southwest. Nat. 37:293–298). *Pituophis c. sayi* has been found in a ponderosa pine in Montana (at 7.4 m; Amstrup and McEneany 1980. Wilson Bull. 92:402), a cottonwood in Alberta (3.5 m; Bullock 1981. Bluejay 39:139–140), a willow tree in Colorado (4.6 m; Niedrach 1971. Wilson Bull. 83:317–318), and a bur oak tree in Minnesota (2–3 m, N = 3; Maxson 1981. The Loon 53:61–62). The purpose of this note is to synthesize these earlier records with my observations of arboreal behavior in Nebraska *P. c. sayi*.

FIG. 1. Adult *Pituophis catenifer sayi* (Bullsnake) negotiating the relatively smooth bark of a birch tree, 3.1 m above ground level.

On 29 June 2013 at 1730 h an adult *P. c. sayi* (total length = 140 cm) was first observed moving on the ground ca. 30 m from a large ornamental birch tree (*Betula* cf. *pendula*; DBH 99 cm; height ca. 20 m) in a residential yard in the housing area of the Crescent Lake National Wildlife Refuge, just north of Gimlet Lake, Garden Co., Nebraska, USA. On reaching the tree the snake proceeded to move up the rough lower bark on the tree ca. 3.1 m until that bark transitioned to the smoother upper bark typical of a birch tree (Fig. 1). The snake continued climbing upward in a manner strikingly similar to that of *Pantherophis* species. At 4.0 m, the snake reached the first whorl of branches and proceeded to move laterally through the branches, with frequent tongue-flicking, in a manner that suggested it was foraging. Several *Quiscalus quiscula* (Common Grackle) nests were present much higher up in this same tree, from which the young had recently fledged. The snake repeatedly foraged out 3–4 m from the trunk in these branches for ca. 15 min, and then returned to the trunk and descended to the ground. The snake had reached a maximum height of 4.6 m. It is assumed that the snake was attracted to this particular tree because of the odors associated with the fledging grackles (Eichholz and Koenig, *op. cit.*).

In 2010, at this same site, another large adult *P. c. sayi* was observed attempting to climb a large cottonwood tree (DBH 122 cm), but was accidentally disturbed when its head had reached a height of only 3 m. In addition, Bullsnakes at this site have been observed on two occasions to climb electrical conduit pipes on the sides of residences to reach Barn Swallow nests under the eaves at heights of 3.8 m. Despite the fact that *P. c. sayi* is primarily a prairie inhabitant, the combined records now available suggest that this species is much more scansorial than generally appreciated.

JOHN B. IVERSON, Department of Biology, Earlham College, Richmond, Indiana 47374, USA; e-mail: johni@earlham.edu.

***PLATYCEPS COLLARIS* (Collared Dwarf Racer). REPRODUCTION.** *Platyceps collaris* is known from Bulgaria, Israel, Jordan, Lebanon, Syria, and Turkey (Bar and Haimovitch 2011. A Field Guide to Reptiles and Amphibians of Israel. Pazbar Ltd., Herlizya, Israel. 245 pp.). Anecdotal information on reproduction of female *P. collaris* is in Bar and Haimovitch (*op. cit*), Baran and Atatür (1998.Turkish Herpetofauna (Amphibians and Reptiles). Republic of Turkey, Ministry of Environment, Ankara. 214 pp.). and Stojanov et al. 2011. Die Amphibien und Reptilien Bulgariens. Edition Chimaira, Franfurt am Main. 591 pp.). In this note I present the first information on the testicular cycle of *P. collaris*.

A sample of 13 male *P. collaris* (SVL = 630.9 mm ± 105.4 SD, range = 437–647 mm) collected 1950–2012 in Israel and placed in the Zoological Museum of Tel Aviv University (TAUM), Israel (by region) was examined: HaSharon TAUM 42, 43, 4540, 4797, 7084, 10329, 13459; Hermon Mountain TAUM 13212; Jordan Valley TAUM 14119; Lower Galil TAUM 16114; Southern Coastal Plain TAUM 2122; Yizreel Valley TAUM 36, 3858. A small slit was made in the left side of the abdomen and the left testis was removed for histological examination. Testes were embedded in paraffin. Sections were cut at 5 µm and stained by Harris' hematoxylin followed by eosin counterstain. Histology slides are deposited at TAUM.

Three stages were observed in the testicular cycle (Table 1); (1) regressed, seminiferous tubules are reduced in size and contain spermatogonia with interspersed Sertoli cells; (2) recrudescence, a proliferation of germ cells occurs for the next period of spermiogenesis (= sperm formation), primary or secondary

TABLE 1. Monthly stages in the testicular cycle of 13 adult male *Platyceps collaris* from Israel.

Month	N	Regressed	Recrudescence	Spermiogenesis
January	2	0	2	0
March	2	0	2	0
April	2	0	0	2
May	3	0	0	3
June	1	0	0	1
July	2	1	0	1
December	1	0	1	0

spermatocytes predominate; (3) spermiogenesis, seminiferous tubules are lined by sperm or clusters of metamorphosing spermatids. The smallest reproductively active male (TAUM 4540) exhibited spermiogenesis and was collected in June. The period of sperm production encompassed April into July. This period of sperm production is compatible with the times of egg deposition in *P. collaris* in Bar and Haimovitch (*op. cit*) (August) and Stojanov (*op. cit*) (July).

I thank Shai Meiri (TAUM) for permission to examine *P. collaris*, Erez Maza (TAUM) for facilitating the loan and the National Collections of Natural History at Tel Aviv University for providing samples of *P. collaris* used in this study.

STEPHEN R. GOLDBERG, Whittier College, Department of Biology, PO Box 634, Whittier, California 90608, USA; e-mail: sgoldberg@whittier.edu.

***PSEUDOBOA NIGRA* (Black False Boa). ENDOPARASITES.** Pentastomids are common parasites of vertebrate respiratory tracts, especially of reptiles (Riley 1986. Adv. Parasitol. 25:45–128). *Raillietiella furcocerca* is a generalist parasite and is known to infect eight species of snakes (Almeida et al. 2008. Braz. J. Biol. 68:201–205). Herein, we report the presence of *R. furcocerca* as a parasite of a ninth species, *Pseudoboa nigra*. On 28 January 2011, at ca. 2200 h, we collected a road-killed specimen of *P. nigra* near the municipality of Chupinguaia, Rondônia state, Brazil and deposited it at Coleção Zoológica de Vertebrados da Universidade Federal de Mato Grosso, Cuiabá, Brazil (UFMT-R 9504). The respiratory tract of the snake was removed and a search for pentastomids was carried out under stereomicroscopy. One adult female *Raillietiella furcocerca* was found in the nasopharynx. After identification, the material was deposited in the Parasitological Collection of the Universidade Regional do Cariri (URCA-P 400).

***PYTHON MOLURUS BIVITTATUS* (Burmese Python). MINIMUM SIZE AT MATURITY.** *Python molurus* is one of the largest snakes in the world and has been a mainstay of the pet trade for several decades, resulting in establishment of an invasive population in South Florida. Ironically, the biology of this species in its native range is poorly known and we know considerably more about the invasive population than we do about native populations in Asia. *Python molurus* in Florida are known to grow to over 5 m total length with clutch sizes of up to 87 eggs (Krysko et al. 2012. IRCF Reptiles and Amphibians 19:267–270). However, we still know little about patterns of growth, maturation, and reproduction in wild *P. molurus*. Here we report the smallest gravid female *P. molurus* found thus far in the wild.

FIG. 1. Female *Python molurus bivittatus* measuring 210 cm total length (185 cm SVL) and containing eleven viable eggs collected in Everglades National Park, Florida, representing the smallest known wild gravid female of the species.

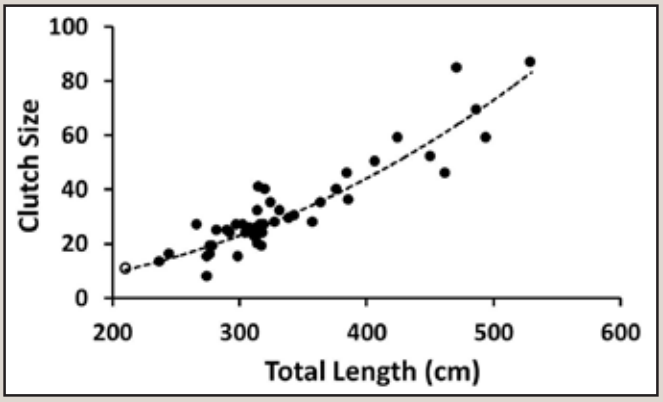

FIG. 2. Relationship between body length and clutch size for 49 female *Python molurus* removed from the invasive population in South Florida. Clutch size includes oviductal and brooded eggs, whether viable or unfertilized. The female described in this note is indicated by an open point.

At 2252 h on 27 May 2013 (22.8°C; light rain) a female *P. molurus* (Everglades National Park Accession # EVER-00888; Catalog # EVER 80679) was captured crossing the Main Park Road in Everglades National Park, in the vicinity of Paurotis Pond (25.28367°N, 80.798355°W; datum WGS84). When euthanized and necropsied, the snake (SVL = 185 cm, total length = 210 cm, mass = 5096 g) was found to contain 11 oviductal, shelled eggs (Fig. 1). All eggs were viable, based on the presence of developing embryos. This is the smallest gravid female *P. molurus* captured in Florida, 23 cm shorter (SVL) than the next smallest gravid female (Fig. 2). The clutch size is among the smallest reported in Florida, but is slightly larger than expected based on body length-clutch size relationships for females in this population (Fig. 2). Older literature sources have reported that female *P. molurus* reach maturity at around 270 cm total length, substantially longer than this individual (Wall 1921. Ophidia Taprobanica or the Snakes of Ceylon. Government Printer, Colombo. 581 pp.; Lederer 1956. Die Aquarien-und Terrarien-Zeitschrift 9:243–248). We are unaware of any other published accounts of size at maturity for this species.

The relatively small size of this female suggests that *P. molurus* in Florida may reach maturity rapidly. Overfed captive individuals can easily attain body lengths greater than 200 cm in

one year (Ross and Marzec 1990. The Reproductive Husbandry of Pythons and Boas. Institute for Herpetological Research, Stanford, California. 270 pp.). Growth rates of wild *P. molurus*, either in Florida or in Asia, are unknown, but are undoubtedly slower. However, a demographic analysis of Florida *P. molurus* suggests that females reach 200 cm SVL by two years of age (Willson et al. 2010. Biol. Invasions 13:1493–1504). Taken together, these data suggest that at least some *P. molurus* in Florida reach reproductive maturity at age two. Rapid growth and high reproductive potential of this species are likely strong drivers of its success as an invasive species (Reed et al. 2012. Integr. Zool. 7:254–270).

***RHINOCHEILUS LECONTEI TESSELLATUS* (Texas Longnose Snake). PREDATION.** *Rhinocheilus lecontei tessellatus* is a small to medium-sized colubrid snake distributed across the western two-thirds of Texas (Dixon 2013. Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 447 pp.). Little is known concerning the natural history of *R. lecontei*, which probably reflects its nocturnal nature. The few documented predators of *R. lecontei* include a conspecific (Lane 2009. Herpetol. Rev. 40:358), *Coluber* (=*Masticophis*) *flagellum* (Coachwhip; Kasper 2013. Herpetol. Rev. 44:334), and nesting *Buteo jamaicensis* (Red-tailed Hawk; Steenhof and Kochert 1985. Oecologia 66:6–16). Herein I describe predation of *R. l. tessellatus* by a novel mammalian predator, *Ictidomys parvidens* (Rio Grande Ground Squirrel; previously considered a subspecies of the Mexican Ground Squirrel, *Spermophilus mexicanus parvidens*).

At ca. 0920 h on 22 May 2012, I observed a male *I. parvidens* running along a graded dirt road with an object dangling from its mouth at Lake Alan Henry Wildlife Mitigation Area, ca. 11 km S, 26 km W of Clairemont, Kent Co., Texas, USA. The squirrel came to a stop and fed for 1–2 minutes then dropped the item and retreated after I clapped my hands repeatedly. I salvaged a small section of the cloacal region of a male *R. l. tessellatus*. The very fresh condition of the remains indicated this was a predator-prey event and not carrion feeding. Also of note was the ground squirrel's feeding behavior. Of the 37 mm of remaining carcass, 19 mm was pre-vent and 18 mm was post-vent. Incisor marks indicated that the ground squirrel fed at both ends toward the vent almost evenly, undoubtedly segregating the cloacal area that contained pungent musk and/or feces produced prior to death. Generally an omnivore of seasonal vegetation and insect prey, *I. parvidens* is known to take carrion and some small living vertebrate prey (Davis and Schmidly 1994. The Mammals of Texas. Texas Parks and Wildlife Press, Austin. 338 pp.). This account documents both the first known mammalian predator of *R. lecontei*, and *I. parvidens* preying on any species of snake.

STEPHEN KASPER, Lake Alan Henry Wildlife Mitigation Area, Parks and Recreation Department, City of Lubbock, Lubbock, Texas 79401, USA; e-mail: skasper@mail.ci.lubbock.tx.us.

***SALVADORA BAIRDI* (Baird's Patch-nosed Snake). DIET.** Little is known about the diet of *Salvadora bairdi*. The literature mentions that it consumes amphibians, small mammals, and especially diurnal lizards and their eggs (Lemos-Espinal and Smith 2009. Anfibios y Reptiles del Estado de Chihuahua, México. UNAM, Tlalnepantla, México, México. 613 pp.; Uribe-Peña et al. 1999. Anfibios y Reptiles de las Serranías del Distrito Federal, México. Instituto de Biología, México, Distrito Federal, México. 119 pp.). However, no mammalian prey have been identified to species. Here we report the first record of predation on *Baiomys taylori* (Northern Pigmy Mouse) by *S. bairdi*.

On 28 July 2013, at 2020 h, a female *S. bairdi* (SVL = 585 mm; tail length = 210 mm; 30 g) was found beneath a rock at Mesa del Huarache, Municipality of Calvillo, Aguascalientes, Mexico (21.900171°N, 102.828405°W, datum WGS84; elev. 2321 m). The habitat at the location consists of grassland with patches of oak forest and tropical scrub forest ecotone. Manual palpation caused the snake to regurgitate a partially digested *B. taylori* (UAA-CV-R255), the only pigmy mouse known to occur in the area.

RUBÉN A. CARBAJAL-MÁRQUEZ, Centro de Investigaciones Biológicas del Noroeste, Instituto Politécnico Nacional No.195 Col. Playa Palo de Santa Rita Sur, C. P. 23096, La Paz, Baja California Sur, México (e-mail: redman031@hotmail.com); **ZAIRA Y. GONZÁLEZ-SAUCEDO**, Universidad Autónoma de Querétaro, Facultad de Ciencias Naturales, Cerro de las Campanas s/n, Querétaro, Querétaro 76017, México; **GUSTAVO E. QUINTERO-DÍAZ**, **ERIC A. RIVAS-MERCADO** and **KATTIA AGUIRRE-RAMÍREZ**, Universidad Autónoma de Aguascalientes, Centro de Ciencias Básicas, Departamento de Biología, Avenida Universidad No. 940, Aguascalientes, Aguascalientes 20131, México.

***THAMNOPHIS PULCHRILATUS* (Yellow-throated Gartersnake). DIET AND DEFENSIVE BEHAVIOR.** Virtually nothing is known about the natural history of *Thamnophis pulchrilatus*, but it is thought to consume leeches, worms, fish, and amphibians, like other mountain garter snakes (Rossman et al. 1996. The Garter Snakes: Evolution and Ecology. Animal Science Series, Univ. Oklahoma Press, Norman, 332 pp.; Ramírez-Bautista et al. 2009. Herpetofauna del Valle de México: Diversidad y Conservación. UAEH, CONABIO. Pachuca. 213 pp.). Additionally, its defensive behavior is unknown. Here we document a new species in the diet of *T. pulchrilatus* and its defensive behavior.

On 28 August 2013, at 2012 h, a female *T. pulchrilatus* (SVL = 434 mm; tail length = 109 mm; 11 g) was found beneath a rock at Mesa del Huarache, Municipality of Calvillo, Aguascalientes, México (21.907151°N, 102.825820°W, datum WGS84; elev. 2332 m). The habitat was grassland with patches of oak forest, and tropical scrub forest ecotone. When we flipped the stone, the snake tried to escape, and finally formed concentric rings, hiding the head, and raising its tail in sinuous movements while secreting musk. Following capture, the snake was palpated and regurgitated a partially digested *Hyla eximia* (Mountain Treefrog; UAA-CV-R257). Similarly, on 15 August 2013 at the same locality, another female (SVL = 510 mm; tail length = 132 mm; 20 g; 21.882258°N, 102.847628°W; elev. 2380 m) was discovered basking in the grass and displayed the same defensive behavior. On 12 June 2010, at Ciénega de Quijas, Sierra el Laurel, Aguascalientes (21.727264°N, 103.709210°W, datum WGS84; elev. 2362 m) another specimen was found beneath a rock. It flattened the anterior half of its body, including the head, showing the bright blue in the interspaces between the scales for at least 30 sec, then tried to escape.

RUBÉN A. CARBAJAL-MÁRQUEZ, Centro de Investigaciones Biológicas del Noroeste, Instituto Politécnico Nacional No.195 Col. Playa Palo de Santa Rita Sur, C.P. 23096, La Paz, Baja California Sur, México (e-mail: redman031@hotmail.com); **ZAIRA Y. GONZÁLEZ-SAUCEDO**, Uni-

versidad Autónoma de Querétaro, Facultad de Ciencias Naturales, Cerro de las Campanas s/n, Querétaro, Querétaro 76017, México; **GUSTAVO E. QUINTERO-DÍAZ**, Universidad Autónoma de Aguascalientes, Centro de Ciencias Básicas, Departamento de Biología, Avenida Universidad No. 940, Aguascalientes, Aguascalientes 20131, México.

***TROPIDODRYAS STRIATICEPS* (Jiboinha). DIET.** *Tropidodryas striaticeps* is a semi-arboreal snake widely distributed throughout eastern Brazil (Guedes and Marques 2011. Check List 7:78–82; Sousa et al. 2012. Biota Neotrop. 12:35–49). Despite its wide distribution, little is known about its ecology. *Tropidodryas* spp. are known to feed on lizards, frogs, rodents, and small birds (Vrcibradic et al. 2012. Herpetol. Notes 5:471–472). Here we report two cases of predation by *Tropidodryas striaticeps* on novel prey items.

On 11 March 2009 at the municipality of Juiz de Fora, Minas Gerais, Brazil (21.742667°S, 43.29225°W, datum WGS 84; elev. 709 m), a male *T. striaticeps* (SVL = 513 mm, tail length = 150 mm) was collected in an Atlantic Forest fragment. After being handled, the specimen regurgitated a bird, *Sporophila* sp. (Emberizidae). Both the snake and the bird are deposited in Coleção Herpetológica da Universidade Federal de Juiz de Fora (voucher number: CHUFJF 0598A and CHUFJF 0598B). The advanced stage of prey decomposition precluded species identification but three species of *Sporophila* are known from the study area: *S. frontalis*, *S. falcirostris*, and *S. caerulescens* (Manhães and Loures-Ribeiro 2011. Biota Neotrop. 11:275–286). On 30 January 2013 at the municipality of Castelo, Espírito Santo, Brazil (20.511839°S, 41.090467°W, datum WGS 84; elev. 1453 m), a female *T. striaticeps* (SVL = 761 mm, tail length = 206 mm) was collected in a rock outcrop beside a stream in an Atlantic Forest fragment. We found the snake feeding on a recently dead lizard, identified as *Tropidurus torquatus*. Both the snake and the lizard are deposited in Coleção Herpetológica da Universidade Federal de Minas Gerais (voucher numbers: UFMG 1692–1693).

SCG thanks Cordenação de Aperfeiçoamento de Pessoal de Nível Superior (CAPES) for financial support and also ICMBio for authorization of animal capture (number 17074-1). BMS thanks Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq) for financial support. We thank Celso Rios for field assistance.

SAMUEL CAMPOS GOMIDES (e-mail: samuelbio@hotmail.com), **MARCUS THADEU TEIXEIRA SANTOS**, **BRUNO BARBOSA FEHLBER**, Programa de Pós-Graduação em Zoologia, Departamento de Zoologia, Instituto de Ciências Biológicas, Universidade Federal de Minas Gerais, Av. Antônio Carlos, 6627, CEP: 31270-901, Belo Horizonte, MG, Brazil; **MARCO ANTÔNIO MANHÃES**, Instituto de Ciências Biológicas, Universidade Federal de Juiz de Fora, Campus Universitário, Bairro São Pedro, CEP 36036-900, Juiz de Fora, MG, Brazil; **BERNADETE MARIA DE SOUSA**, Departamento de Zoologia, Instituto de Ciências Biológicas, Universidade Federal de Juiz de Fora, Bairro Martelos, 36036-900, Juiz de Fora, MG, Brazil; and **PAULO CHRISTIANO DE ANCHIETTA GARCIA**, Programa de Pós-Graduação em Zoologia, Departamento de Zoologia, Instituto de Ciências Biológicas, Universidade Federal de Minas Gerais, Av. Antônio Carlos, 6627, CEP: 31270-901, Belo Horizonte, MG, Brazil.

***TROPIDOPHIS MACULATUS*. MAXIMUM SIZE.** On 11 February 2007, CAM collected a female *Tropidophis maculatus* in Río Baracoa, Bauta, La Habana, Cuba, resting under a stone in burned grassland. This specimen (MFP 12506, Museo de Historia Natural "Felipe Poey," Facultad de Biología, Universidad de La Habana, La Habana, Cuba) measured 450 mm SVL and 495 mm total length. The maximum length previously reported for this species is 375 mm SVL in a male (Domínguez and Moreno 2006. Herpetol. Rev. 37:355–356), but Bibron (1840. *In* de la Sagra [ed.], Historia Física, Política y Natural de la Isla de Cuba, vol. IV, pp. 1–143, Imprenta y Litografía de Maulde et Renou, Paris), in the original description of this species, measured an individual that was 419 mm SVL. Bibron (*op. cit.*) did not note the sex nor voucher number; he only stated the specimens formed part of Mr. la Sagra's collection. Thus, our specimen appears to be the largest *T. maculatus* on record.

Studies on Venomous Reptiles in Zoos and Aquariums: Part II—True Vipers, Fea's Viper, Mole Vipers, Pitvipers, Venomous Lizards, Conclusion

JAMES B. MURPHY
Smithsonian National Zoological Park
3001 Connecticut Ave., NW
Washington DC 20008, USA
E-mail murphyj@si.edu

THERE'S NO DOUBT ABOUT IT: SNAKES *ARE* FASCINATING! THEY MAY NOT INSPIRE MUCH AFFECTION, BUT THEY CERTAINLY GENERATE INTEREST, THE CROWDS THAT THRONG REPTILE HOUSES AT ZOOS THROUGHOUT THE WORLD TESTIFY TO THE EXTRAORDINARY APPEAL OF THESE REMARKABLE REPTILES. I CAN FULLY SYMPATHIZE WITH THIS FASCINATION, BECAUSE I FEEL THE SAME WAY --- EVEN AFTER TWENTY YEARS OF STUDYING THESE MYSTERIOUS ANIMALS.

--RICHARD SHINE, *AUSTRALIAN SNAKES, A NATURAL HISTORY*, 1991.

TRUE VIPERS

Africa is truly blessed by having a number of spectacular true vipers and members of the family Atractaspididae. As a result, zoo herpetologists have focused attention on including them in their collections. One of the most desirable assemblages includes members of the genus *Bitis* (Figs. 1, 2, 3). At Dallas Zoo, we specialized in this group: Puff Adder (*Bitis arietans*), Berg Adder (*B. atropos*), Horned Adder (*B. caudalis*), Many-horned Adder (*B. cornuta),* both species of Gaboon Vipers (*B. gabonica* and *B. rhinoceros*), Rhinoceros Viper (*B. nasicornis*), Peringuey's Viper (*B. peringueyi*), Namaqua Dwarf Adder (*B. schneideri*), and Worthington's Viper (*B. worthingtoni*). All were excellent exhibit ophidians except the Peringuey's Viper, which was small and insisted on burrowing with only eyes visible. Many *Bitis*, *Atheris*, and *Azemiops* were photographed by John H. Tashjian at Dallas Zoo and may be seen in *True Vipers: Natural History and Toxinology of Old World Vipers* (Mallow et al. 2002).

In 1915, Edward Boulenger published notes on feeding captive snakes at London Zoo, including Puff Adders. Biella et al. (1989) recorded the reproductive biology of the Puff Adder and Gaboon Viper and added requirements for nourishment, growth, and care. Meyer-Holzapfel (2007) discussed reproduction of the Puff Adder at Berne Zoo in Switzerland and Almandarz (2007) at Lincoln Park Zoo in Chicago. At Manyeleti Reptile Centre, Eastern Transvaal, South Africa, Haagner (1990) outlined techniques for maintaining captives which led to reproduction and dermatophagy (1991). One lived at San Diego Zoo for 12 years, 10 months. A Puff Adder gave birth to 156 young, two of which were stillborn (Janacek 1976). Murphy (1973) removed a deficient fang mechanism in a captive Puff Adder. Petzold (in Heichler and Murphy 2008) showed a Puff Adder consuming a shed skin. At Brookfield Zoo, Snedigar and Rokosky (1949) reported on newborn Gaboon Vipers (*B. gabonica*). Jacobs and Belcher (1983) noted captive reproduction in the West African Gaboon Viper (*B. rhinoceros*) at Rio Grande Zoological Park. Vandeventer and Schmidt (1977) performed a caesarean section on a Western Gaboon Viper. A specimen fasted for 30 months at Frankfurt/Main Zoo (Petzold, in Heichler and Murphy 2008). Banks (2002) reported on the birth of Rhinoceros Vipers (*B. nasicornis*) at Melbourne Zoo in 1997.

An interesting paper by John Phillips and Allison Alberts at San Diego Zoo in 1992 explored the predatory behavior in hatchling monitor lizards (*Varanus albigularis*) that may encounter snakes, such as Horned Adders, as both predators and prey—they conclude by saying— "Immediately after hatching, monitor lizards are naive to all prey items, thus correct assessment of snake prey is paramount for survival…Attack was inhibited in trials in which unrestrained prey were tongue-flicked, suggesting that chemical cues contained in snake skins mediate avoidance of venomous snakes. Selection for the ability to perceive snake integumental chemicals may be especially strong in species that both consume and are consumed by snakes."

There is little published information on the African vipers of the genera *Atheris, Proatheris,* and *Montatheris*. At Dallas Zoo, the following species were kept; Usambara Bush Viper (*Atheris ceratophora*), West African Bush Viper (*A. chlorechis*), Ashe's Bush Viper (*A. desaixi*), East African Bush Viper (*A. squamigera*; Fig. 4), African Hairy Bush Viper (*A. hispida*), Great Lakes Bush Viper (*A. nitschei*), and Lowland Swamp Viper (*P. superciliaris*). All of the

COURTESY OF GERARD VISSER, ROTTERDAM ZOO

FIG. 1. Gaboon Viper (*Bitis gabonica*) from *Reisebilder aus Liberia* by Johann Büttikofer, 1890.

FIG. 2. Boa Constrictor and Rabbit, by Beata Francis in *The Child's Zoological Garden,* 1880. Looks more like a Puff Adder to me! I suspect this rabbit's days may be numbered and the carrot left uneaten.

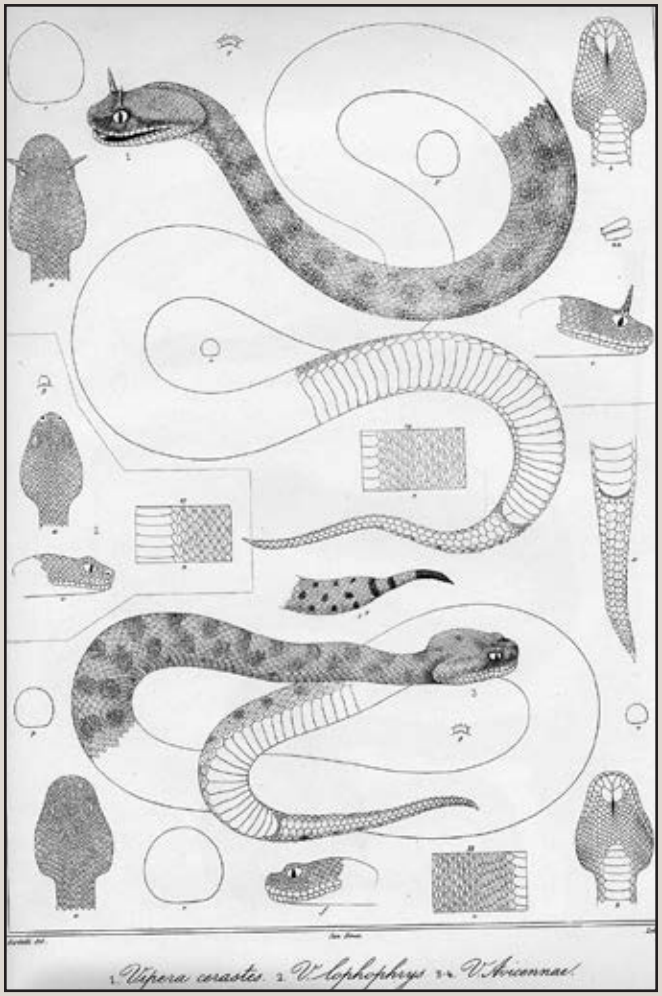

FIG. 3. Illustration from top to bottom of Desert Horned Viper (*Vipera cerastes*, now *Cerastes cerastes*), Many-horned Adder (*Vipera lophophrys*, now *Bitis cornuta*), and Sahara Sand Viper (*Vipera Avicennae*, now *Cerastes vipera*) from *Iconographie Générale des Ophidiens* by Georges Jan and Ferdinando Sordelli,1860–66. This atlas contained 300 plates illustrating the snakes of the world.

above except *hispida* were excellent exhibit snakes; specimens of this species were riddled with internal parasites. Several species (*chlorechis, hispida, nitschei*) occasionally required soaking in water to induce defecation. Some individuals were provoked to strike defensively at small mice in order to elicit feeding; usually the prey was held with the fangs and eventually swallowed. Tom Madsen told me that wild *A. hispida* fed on thin-shelled terrestrial snails which were tried at Dallas Zoo but they were ignored. The only live specimens of Kenyan Mountain Viper (*M. hindii*) I have seen were at Houston and Columbus zoos. Boulenger (1915) discussed feeding in the West African Bush Viper at London Zoo and Freed (1986) from Houston Zoo discussed reproduction. In 1936, specimens of Lowland Swamp Viper were collected by Hugh Cott for London Zoo but all refused to feed. Morgan (1988) provided husbandry information on seven snakes at Transvaal Snake Park. This species produced three litters (5–7 individuals each) at Dallas Zoo and all fed well.

Night Adders (*Causus*) are poorly known from captive specimens. The late John Mehrtens had two types (*C. rhombeatus, C. resimus*) on display in Ft. Worth Zoo collection in the mid-1960s and which fed primarily on anurans (pers. comm.). The same species were kept at Columbus Zoo (E. Smith, pers. comm.) in the 1970s.

At Columbus Zoo, Goode (1979) described reproduction in the Saw-scaled Viper (*Echis colorata*) and Cherlin (1985) explored reproduction of the Iranian Saw-scaled Viper (*E. multisquamatus*) in the Tashkent Zoo. Mehrtens (1950) elaborated on keeping the Saw-scaled Viper in captivity at Ft. Worth Zoo. The late curator Mike Goode at Columbus Zoo told me that the Saw-scaled Viper attained the fourth generation at that institution; this was a significant achievement.

Russell's Vipers (*Vipera russelli,* now *Daboia russelli*) are often kept in zoo collections. Naulleau and Van Den Brule (1981) published an excellent overview on feeding, growth, moult, and venom production in captivity. Meyer-Holzapfel (1969) elaborated on reproduction at Berne Zoo. From the Frankfurt a. M. Zoo, Backhaus (1972) discussed the geographical variation of venom toxicity and antivenin efficacy in Saw-scaled and Russell's vipers.

Many European viper species are at risk. One example is the Hungarian Meadow Viper (*Vipera ursinii rakosiensis*). A Population and Habitat Viability Assessment (PHVA) was held in a workshop on 5–8 November 2001 at Budapest Zoo, Hungary. This collaborative workshop was hosted by the Budapest Zoo, Conservation Breeding Specialist Group (SSC / IUCN), and Zoo Tiergarten Schönbrunn, Vienna. The IUCN recommended the following: "Habitat protection alone is not sufficient if the expressed goal of the World Conservation Strategy, the maintenance of biotic diversity, is to be achieved. Establishment of self-sustaining captive populations and other supportive intervention will be

FIG. 4. Publications of London Zoological Society between 1860–1921 had beautiful snake illustrations such as this Green Bush Viper (*Atheris squamigera*).

FIG. 5. European Viper (*Vipera ammodytes)* from *Vorstellung allerhand Thiere…* by Johann Daniel Meyer, 1752.

FIG. 6. This illustration appears to be Asp Viper (*Vipera aspis*), a taxon native to N Italy where Ulisse Aldrovandi lived. From *Ulyssis Aldrovandi… Serpentum, et draconum historiæ libri duo. / Bartholomæus Ambrosinvs ... opvs concinnauit ... Sumptibus M.A. Bernie* ... in 1640.

needed to avoid the loss of many species, especially those at high risk." (Korsós, Z. 2002. The biology and ecology of *Vipera ursinii rakosiensis*. In *Workshop Report*, p. 61. 2002). Gravid females of this critically endangered snake were maintained and young were raised at the Zoological Garden, Budapest (Újvári et al. 2000).

Petzold (see Heichler and Murphy 2008) described courtship, pre-copulatory and copulatory behavior, combat, feeding, captive management, reproduction, longevity, and other aspects in the Viperidae, including *Vipera ammodytes* (Fig. 5), *V. aspis* (Fig. 6), *V. berus*, *V. kaznakovi*, *V. lebetina*, *V. russelli*, and *V. ursinii*. Naulleau (1971, 1984, 2007; Naulleau and Detrait 1984) discussed fertility and rearing the Asp Viper (*V. aspis*) in captivity. Petzold (1980) provided statistical data on birth weights of the Common Viper (*V. berus*; Fig. 7).

Since 1996, Jeff Ettling from Saint Louis Zoo has focused efforts on the captive management and reproduction of mountain vipers, *Montivipera*, of the Near East. In 2004, the Zoo developed its new Conservation Division, the Wildcare Institute—there are twelve different Conservation Centers focusing on endangered species and their habitats. The Center for Conservation of Near East Mountain Vipers will focus on an initiative to ensure the future of mountain vipers in the wild (Ettling 2005).

There are eight species in the mountain viper *Montivipera xanthina* complex found in southeastern Europe, Asia Minor, Armenia, and western Asia. Nilson and Andrén (2000) have identified risks. Over the past 20 years, the combination of habitat alteration, over-collection, and unnaturally high mortality resulting from human persecution has drastically reduced many mountain viper populations. Five of the eight species are now listed by the IUCN as vulnerable, endangered, or critical.

In June 2004, the Center started an inaugural study on the Armenian Viper, *M. raddei*, seriously at risk because the population has decreased 88% over the past 20 years, due largely to habitat alteration and over-collection (Ettling 2005; Ettling et al. 2013). These radio-telemetry and mark/recapture elements focus on home range size, seasonal activity patterns, habitat preferences,

Fig. 7. Many of the drawings in Bernard-Germain-Étienne de la Ville-sur-Illon, Compte de Lacepède's publications show snakes striking at prey. The Common Viper should handle the anuran prey with ease but the Horned Viper below will certainly have a difficult time swallowing its avian prey. This plate is from *Histoire naturelle deLacépède, comprenant les cétacés, les quadrupèdes ovipares, les serpents et les poissons* in 1860.

Fig. 8. Illustration of True Viper heads with horns from *Erpétologie générale by* A. M. C. Duméril, G. Bibron, and A. Duméril, 1854. Current common and scientific names are #1 Sand Viper (*Vipera ammodytes*); #2 Rhinoceros Viper (*Bitis nasicornis*); #3 possibly Sahara Sand Viper (*Cerastes vipera*); #4 Many-Horned Adder (*Bitis cornuta*); #5 Persian Horned Viper (*Pseudocerastes persicus*).

COURTESY OF KRAIG ADLER AND TIM PERRY

and demography, and involve five institutions: Saint Louis Zoo, Detroit Zoological Institute, Russian Academy of Sciences, Armenia Ministry of Nature Protection, and Tula Exotarium, Russia. Studies of captive vipers have provided information on reproduction and behavior (Ettling 1996; Ettling and Marfisi 2002). Dutton and Taylor (2003) compared pre-and post-hibernation morphometry, hematology, and blood chemistry in 31 viperid snakes at the zoo.

The situation is similar in Iran in terms of vipers at risk. Kian et al. (2011, 2013) discussed captive management and reproductive biology of Latifi's Viper (*Montivipera latifii)* and Zanjan Viper (*M. albicornuta*) at Razi Institute and Tehran University. Mamet and Kudryavtsev (1996) bred Latifi's Viper at Moscow Zoo.

In Russia, Sergei V. Mamet and Sergei V. Kudryavtsev from Moscow Zoo have published on Caucasian Vipers (*Vipera ammodytes transcaucasiana* and *V. kaznakovi*) and the latter coauthored a guide for keeping venomous snakes in 1997. Bozhansky and Kudryavtsev (1986) discussed Caucasian Viper ecology and breeding in captivity. Bozhanskyi and Kudryavtsev (1982) outlined special aspects in captive maintenance of rare vipers of USSR. Khutoryansky (1968) diagnosed the cause of death of Levantine Viper (*V. lebetina turanica*) at Moscow Zoo. Kudryavtsev and Mamet (2011) reported on husbandry and reproduction on Field's Viper *Pseudocerastes persicus fieldi* and Armenian Viper (1991) at Moscow Zoo. The Levantine Viper subspecies *V. lebetina turanica* and *V. l. obtusa* reproduced at Leningrad Zoo (Igolkina 1988). At Tula Exotarium, many important articles were written on terrarium science: Orlov (1982), Orlov and Dmitriev (198), Orlov and Ryabov (1991). Other Russian papers included Pestinsky (1939), Vassiliev et al. (1997), and Zinyakova (1964, 1966) and Zinyakova et al. (1972).

At Dallas Zoo, Murphy and Barker (1980) reported on courtship and copulation of the Ottoman Viper (*Vipera xanthina*). Because the snakes were positioned next to the viewing glass, they were able to see the extrusion of hemipenes into the female's cloaca and the color changes of the organ as it became turgid. At the same zoo, Perry and Blody (1986) described courtship and reproduction in Cretan Vipers (*V. lebetina schweizeri*).

Hans-Werner Herrmann, former herpetological curator at Cologne Zoo and Aquarium in Germany, has published

FIG. 9. Bushmaster from *Los ofidios venenosos del Cauca: métodos empíricos y racionales empleados contra los accidentes producidos por la mordedura de esos reptiles,* by Evaristo García in 1896. Cauca is a Department of Colombia, located in the southwestern part of the country.

several papers on molecular phylogeny and systematics of viperine snakes (1987, 1992, 1995, 1997, Fig. 10). Susan Barnard from Zoo Atlanta and Steve Upton covered parasitism in Palestine Vipers (*V. xanthina palaestinae*) and Ottoman Viper (*V. x. xanthina*).

FEA'S VIPER (AZEMIOPINAE)

Our experiences with Fea's Viper (*Azemiops feae*) at Dallas Zoo parallel those reported by Ken Kardong (1986; pers. comm.). He provided five specimens to the Zoo which were maintained per his suggestions but these were diffident feeders. Two of the five fed on dead mice and one took a skink but refused all amphibians, fish, or lizards. These snakes were susceptible to dehydration even though they were kept on damp paper towels and were provided with drinking water. Overall, our success with the group was marginal. Orlov et al. (2002) described courtship and reproduction in this taxon; they commented that dehydration can be a serious problem. Levens et al. (2000) and Fitzgerald et al. (2008) described a Fenbendazole overdose in four snakes. Recent phylogenies suggest that this taxon is not closely related to Viperinae.

Scott Pfaff told me that a specimen at Riverbanks Zoo is now a 14-year captive and has reproduced, resulting in a single hatchling—this is almost certainly the first captive breeding for this species. He found that this species probably does not thermoregulate and does indeed prefer cool temperatures.

MOLE VIPERS (ATRACTASPIDINAE)

Corkhill et al. (1969) described the striking behavior in Mole Vipers (*Atractaspis*): "1) The snakes of the genus *Atractaspis* have an unusual degree of flexibility of the neck which, coupled with their relatively long fangs, makes it dangerous to handle them in conventional fashion by holding them just behind the head; 2) This flexibility, together with the habits of striking with one fang and with the mouth practically closed, partially twining round the object to be bitten, and clinging on, suggest an adaptation suited to the securing of a prey in constricted underground space." I can attest to the accuracy of both statements. The late Bill Haast from Miami Serpentarium told me in 1966 that he tried

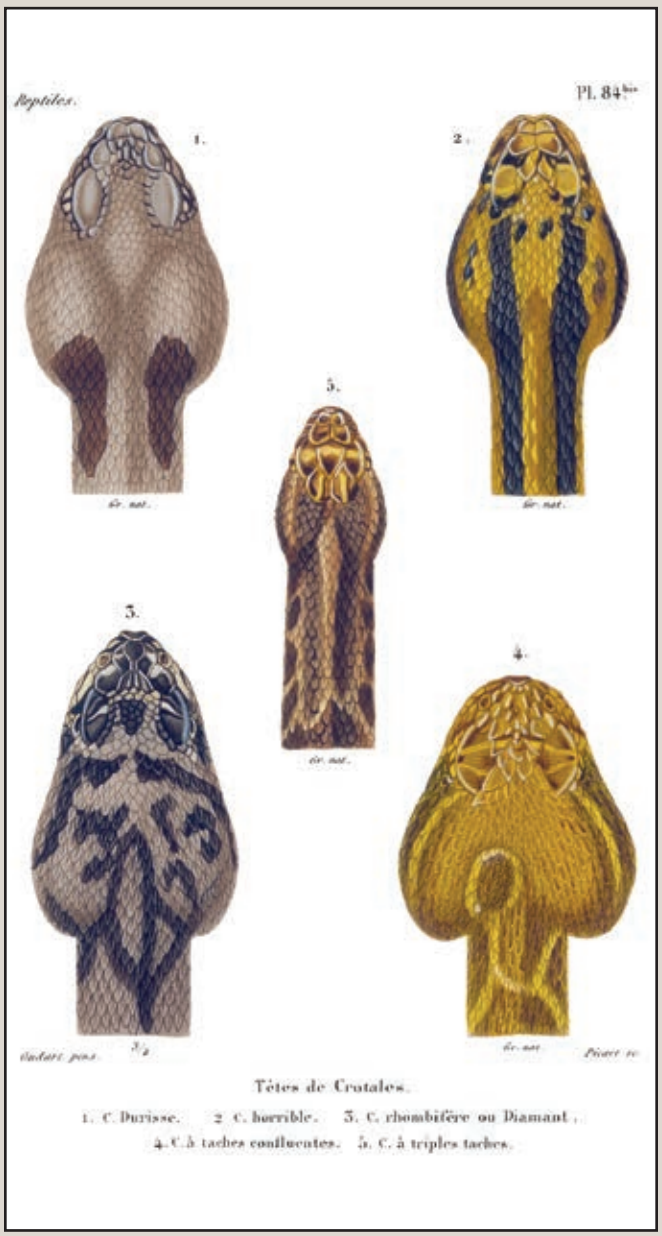

FIG. 10. Illustration of rattlesnake heads from *Erpétologie générale,* by A. M. C. Duméril, G. Bibron, and A. Duméril, 1854. Current common and scientific names are #1 Neotropical Rattlesnake (*Crotalus durissus);* #2 Timber Rattlesnake (*Crotalus horridus*); #3 Eastern Diamondback Rattlesnake (*Crotalus adamanteus*); #4 Western Diamondback Rattlesnake (*Crotalus atrox*); #5 Massasauga (*Sistrurus catenatus*).

COURTESY OF KRAIG ADLER AND TIM PERRY

to control the head of two snakes by holding the neck and was bitten twice for his efforts. At Dallas Zoo, I watched a Mole Viper (*A. dahomeyensis*) spear living snake prey many times and it seemed that the mouth was not opened but prey was struck from the side; this ophidian would only accept living snakes (*Storeria, Nerodia, Thamnophis*) as prey.

PITVIPERS

In 1992, Harry W. Greene and Jonathan A. Campbell presented a grim picture about the future of pitvipers in their abstract for the book *Biology of the Pitvipers*: "Less than a dozen pitvipers

are among approximately 200 snake species previously identified as threatened or endangered worldwide, whereas we estimate that more than half of all crotaline species are now vulnerable to extinction. Taxa with small ranges, narrow habitat preferences, and/or substantial human persecution are of special concern; *Bothriechis* spp., *Crotalus polystictus, Lachesis muta,* and *Sistrurus catenatus* illustrate these issues. Certain taxa should receive special attention for biological, cultural, and/or esthetic reasons. Major goals for pitviper conservation include consideration of these animals in planning for reserves, public education, and facilitation of research on their biology." Can anyone argue that their warnings were taken seriously and the situation has dramatically improved today? I think not! Fortunately, the excellent field and captive program established by Alan Kardon at San Antonio Zoo with emphasis on Mexican pitvipers is an example of progressive thinking, but saving these species is an uphill struggle. At the International Collective Arboreal Symposium in Baltimore, Maryland (April 2013), Kardon showed aerial photographs of the extensive habitat changes wrought by humans throughout Mexico and it was staggering and sobering. Virtually all of the high-elevation ecosystems are at risk, particularly at places where members of the genus *Bothriechis* and montane rattlesnakes are found.

One of the most popular and dramatic zoo exhibits are bushmasters (*Lachesis* spp., Fig. 9). In early days, these were considered delicate captives and mortality was high. In 1918, William Beebe traveled to South America and described his encounter with a bushmaster, eventually captured alive and sent to New York Zoological Society. In 1960, the Zoo again maintained bushmasters and kept them at lower environmental temperatures, believing that this contributed to greater success in maintaining this difficult species; the snake died in 1962 (Dowling 1960, 1961, 1962). Other zoos tried to keep them during the late-1960s but results were mixed. Curator Lou Pistoia at Columbus Zoo was exasperated with the high mortality rate and told me that bushmasters could not be successfully kept in captivity. John Mehrtens was equally frustrated with the high turnover rate at Ft. Worth Zoo. When a gravid wild-caught female laid eggs, he put them in a plastic container and placed it on top of an aquatic turtle enclosure to increase humidity; a heat lamp was suspended above the vessel. Mehrtens drew a line on the floor around the tank and forbid keepers to cross that line—to do so risked termination. On his day off, the bulb was ominously dark. One foolhardy keeper crossed the sacred line to screw in a new bulb, lost his balance, fell into the tank with the eggs— which were promptly eaten by the turtles— and learned to his dismay what hell was really like on Earth. Jon Campbell started his career as assistant supervisor at this Zoo. During a visit, he asked if I had ever seen the Black-headed Bushmaster (*Lachesis melanocephala*) and I replied in the negative. He said that some were placid but others were aggressive and proceeded to remove a large one from its enclosure for a closer look. Naturally, it was one of the latter ones and it proceeded to chase us around the cramped rear section; after much drama, Jon was able to secure the snake but the experience was unsettling.

When I was young, I read the fascinating account in L. N. Wood's book about Raymond L. Ditmars and his experience with a bushmaster: "His first look took no more than a couple of seconds and terminated instantly as he realized that the reptile, forming a striking loop with the whole front half of its body, was deliberately pouring itself toward him. Backing inadvertently into one of the chairs, Ray thrust his crook against the snake, by now well out of its cage.

He saw at once, with alarm, that the reptile had a dexterous way of flowing over the outthrust staff. Faster than he could push it away, it gained ground. There was nothing for him to do but continue to back up. He knew that bushmasters were highly venomous, but no one had told him that they were aggressive and fearless, too.

As he backed warily around the room, Ray's mind worked busily. How was he to get out of this worse-than-silly, this dangerous, situation?

'I can't keep on backing around the room the rest of the night,' Ray told himself impatiently. He wasn't exactly frightened, but this certainly was not a situation he would have chosen.

Just then his eye fell on the broom standing, conveniently, within reach of his staff. He gave it a hard jerk, kicked it behind him, farther from the advancing bushmaster, and picked it up. The snake just then was surging, loops reared, between the rungs of a chair. Ray thrust the broom straight in its face.

Surprised by the attack, the serpent paused and pulled in its head. Coiling, it rattled its tail against the floor. Ray followed up his advantage with several more quick pokes. The snake decided, suddenly, that it had had enough. It turned and made for the tier of cages. Guiding it with the pole, Ray directed it into its own cage and slid shut the panel."

I vowed that my passion would be satisfied when someday I could work with them. In the late 1960s, when a large wild-caught snake (*Lachesis stenophrys*) from Costa Rica arrived at Dallas Zoo, my dream was complete. I noticed a considerable bulge in its body; clearly it had swallowed a large prey item. About a week later, it expelled a compacted bolus of large black and white spines, later identified as a prehensile-tailed porcupine (genus *Coendou*). To this day, I cannot imagine how the snake was able to strike without being impaled by spines or why the snake's entire GI tract was not shredded. To appreciate how dangerous an encounter can be with this porcupine, check out the result of a predation attempt by Schneider's Smooth-fronted Caiman (HR 2013, 44:135).

Because bushmasters were such a challenge, we began to add them to the Dallas Zoo collection, mostly *L. muta*. We did not keep them cool and they thrived but did not reproduce in spite of many attempts by us to induce breeding for many years. Then, when they were moved into a large room, males began to trail females and we observed courtship, copulation, and oviposition. Eggs were artificially incubated and the neonates were hardy captives (Boyer et al. 1989). Later, we studied predatory behavior (Chiszar et al. 1989; Boyer et al. 1995) and saw that these snakes covered their eyes and pits by moving facial skin while holding rodent prey, as described by Chiszar and Radcliffe (1989). Although feeding strikes were impressive, I do not remember a single instance where the snakes struck aggressively or defensively at us.

Greenhall (1936) described care at New York Zoological Park. Burchfield (1975) described the history of captive *L. muta* and *L. stenophrys* at Gladys Porter Zoo in Brownsville, Texas. The first captive hatching of *L. muta* from a wild-caught female occurred at Steinhart Aquarium in San Francisco, California (Switak 1969).

I've always liked the look of rattlesnakes (Fig. 10). When I started in the zoo business, we began to add species to the Dallas Zoo collection. When my friends Barry Armstrong and Jonathan Campbell started traveling to Mexico and Central America each spring and summer in the 1970s, they brought back many living rattlesnakes and kindly placed them on loan to us. At one time, we had every species from mainland Mexico except the Autlán

Fig. 11. Cascabel Rattlesnake from *Buffon's Natural History Abridged…Vol. II.* 1821.

Long-tailed Rattlesnake (*Crotalus lannomi*), mostly collected by this pair of superb field collectors. Herpetologists Edward H. Taylor, Hobart M. Smith, Sherman Minton, Charles Bogert, Roger Conant, and Howard Gloyd told me that even though they had worked in Mexico for years, they had never seen such rattlesnake diversity and were amazed by the assemblage. Gloyd traveled to Dallas virtually every year to visit his family and made a point of stopping in to see what new rattlesnakes were in the collection; although he had published a monograph on them in 1940, he did not have many opportunities to see live specimens. I remember one day when he saw his first Mexican Lance-headed Rattlesnakes (*Crotalus polystictus*), a taxon so rare that it was not pictured in Klauber's monumental work on rattlesnakes in 1956. He was stunned by their beauty and spent many minutes gazing at them with admiration. Although he and Carl Kauffeld described the Totonacan Rattlesnake (*Crotalus durissus totonacus*) in 1940, he told me that he had never seen a living example until his visit. Those were heady days, likely to never be repeated.

Thanks to the generosity of Armstrong and Campbell, we were able to study these rattlesnakes at the Zoo (Armstrong and Murphy 1979; Murphy and Armstrong 1978). They also collected many other Neotropical pitvipers (Murphy 1981; Murphy and Campbell 1987; Radcliffe and Murphy 1983; Murphy and Mitchell 1984). Many of these snakes are pictured in color in *The Venomous Reptiles of Latin America* and *The Venomous Reptiles of the Western Hemisphere* by Jonathan A. Campbell and William W. Lamar. We invited a number of academic colleagues to join us to document behaviors and improve captive maintenance in these snakes: Jonathan Campbell, Charles Carpenter, James Gillingham, David Chiszar, Hobart Smith, and Charles Radcliffe (see literature citations below).

Grace Olive Wiley (1929) may have been the first person to breed rattlesnakes in captivity, at least according to a letter sent to her by Raymond Ditmars. At St. Louis Zoo, Hoessle (1963) observed a breeding pair of Western Diamondback Rattlesnakes (*Crotalus atrox*). Petzold (1963) noted reproduction and development in this species and Cottonmouth Moccasin (*Agkistrodon p. piscivorus*) at the Berlin Tierpark. Gillingham et al. (1983) described courtship, male combat, and dominance at Dallas Zoo. Murphy and Shadduck (1976) reproduced the Eastern Diamondback Rattlesnake (*C. adamanteus*) with a two-headed neonate at Dallas Zoo. Burchfield (1975) described experiences with this species and Antonio and Barker (1983) followed by documenting phenotypic aberrancies. Tryon and Radcliffe (1977) presented reproductive data from captive Lower California Rattlesnakes (*C. enyo*) at Fort Worth Zoo and Denver Zoological Gardens. Tryon (1978) bred a pair of captive Arizona Ridge-nosed Rattlesnakes (*C. willardi*). Ramsay et al. (1996) diagnosed *Salmonella arizona* osteomyelitis in a colony of these snakes at Knoxville Zoo. Carl et al. (1982) documented reproduction in captive Aruba Island Rattlesnakes (*C. unicolor*) at Ft. Worth and Houston Zoos. At Houston Zoo, Peterson (1982) bred Speckled and Neotropical Rattlesnakes (*Crotalus m. mitchelli* and *Crotalus durissus*) (Fig. 11). At Dallas Zoo, Murphy et al. (1979) provided information on the reproductive biology of the Uracoan Rattlesnake (*C. vegrandis*). Interestingly, Loomis and Smith (1987) found that an Aruba Island Rattlesnake (*C. unicolor*) was fertile following caesarean section. Tremper (1980) bred the Santa Catalina Island Rattlesnake (*C. catalinensis*) at Roeding Park Zoo. Carpenter et al. (1976) described male combat in the Rock Rattlesnake (*C. lepidus*) at Dallas Zoo. We produced a number of broods of the Speckled Rattlesnake (*C. m. mitchelli*) at Dallas Zoo. When a BBC film crew asked if we had males that would combat for a David Attenborough nature special, we guaranteed that our young snakes would do so reliably and so they did; we were nervous because they brought all of their equipment from the UK. We carried the snakes in a trashcan to a natural setting and dumped them on the ground; surprisingly, they did not try to escape but locked up immediately. The crew shot, in my view, the best snake combat sequence ever recorded on film. They also filmed open-mouth threat postures in the Mexican Black-tailed Rattlesnake (*C. molossus nigrescens*). From San Diego Zoo, Brown et al. (2008) studied spatial ecology, habitat use, and survivorship of resident and translocated Red Diamond Rattlesnakes (*C. ruber*) and Lemm (2006) produced a field guide that included the rattlesnakes of San Diego County. McCrystal and Ivanyi (2008) discussed translocation of venomous reptiles in the Southwest at Arizona-Sonora Desert Museum. The Museum produced a book entitled *A Natural History of the Sonoran Desert* in 2000 that included species accounts by the staff. This zoo holds regular demonstrations with living venomous reptiles for the visitor which have proven to be very popular (Johnson 2007).

Second-generation births of the Neotropical Rattlesnake (*Crotalus durissus terrificus*) occurred in Dresden and Leipzig (Dathe 1951). Mike Goode (pers. comm.) said that Columbus Zoo bred *C. adamanteus* for three generations. Reports of hybrids from San Diego Zoo include *C. scutulatus* × *C. durissus unicolor* and *C. viridis helleri* × *C. r. ruber* (Perkins 1951; Klauber

1956). The Arizona Sonora Desert Museum (1979 Intern. Zoo News 26 (7/8): 42) reported a hybrid from *Crotalus m. molossus* × *C. viridis cerberus*.

During February 1977, two Dallas Zoo herpetologists were privileged to see an extraordinary encounter between a male Totonacan Rattlesnake (*Crotalus totonacus*), measuring 1.7 m in total length, and an adult Ocelot (*Felis pardalis*) in northeastern Mexico, as described in Armstrong and Murphy (1979), "The animals were below a thick canopy of thorn scrub in early afternoon and the ground beneath the canopy supported little vegetation. A distance of 1.3 m separated the combatants, and the snake was in a defensive posture typical of *C. durissus*, and rattling vigorously. The ocelot remained immobile with the right foreleg raised. When the snake was extended fully with its mouth open after a strike, the ocelot raked with its claws within the snake's mouth, then withdrew the paw before the snake could close its mouth. Later examination of the oral cavity and throat of the snake revealed a number of lacerations in the soft tissue and masseter muscles which were inflicted by the ocelot, but the interstitial skin and scales exterior to the lacerations were not affected. Lacerations were found on the dorsal aspect of the head and neck, but not near the punctures within the snake's mouth or throat. The snake's lower jaw was out of alignment and the mandibular bone was visible when the mouth was open. A large female *C. d. totonacus* was located 15 minutes later, within 12 m of the male. The male rattlesnake was treated for its injuries, but sucumbed about two weeks later (KU 174824). The snake regurgitated a large number of ascarids during the two weeks prior to its death."

At Metro Toronto Zoo, Johnson (1988) observed combat and courtship in the Eastern Massasauga (*Sistrurus c. catenatus*) by comparing field and captive behavior. Lindsey (1979) documented combat behavior in the Dusky Pygmy Rattlesnake (*S. miliarius barbouri*) at Monroe Zoo in Louisiana.

At Smithsonian National Zoological Park, Audubon Zoo, and San Diego Zoo, Chiszar et al. (1985) discovered that duration of strike-induced chemosensory searching (SICS) was not compromised by feeding dead prey to long-time captive snakes; this was an important finding if reintroduction is being considered.

Patrick Burchfield (1982), Gladys Porter Zoo, wrote a seminal paper on the natural history of Taylor's Cantil (*Agkistrodon bilineatus taylori*). Peters (1979) had two generations of the Cantil (*A. bilineatus*) at Taronga Zoo in Sydney, Australia. In 2004, five Taylor's Cantils were born at San Antonio Zoo; today, this taxon is part of a long-term cooperative US zoo breeding program. Allen (1949) described caudal luring in the juvenile Cantil (*A. bilineatus*). Water Moccasins or Cottonmouths (*A. piscivorus*) bred at London Zoo between 1860 and 1861 (Coote 2001). Conant (1933) reported on three generations of Cottonmouths—Moscow Zoo had two (Kudryavtsev et al. 1986) (Fig. 12). The Trans-Pecos Copperhead *(A. contortrix pictigaster*) fed on the Texas Long-nosed Snake and Cliff Swallow (McCrystal and Green 1986).

Early reports of some Neotropical pitvipers were listed as members of the genus *Bothrops*, now comprised of a number of different genera (see Campbell and Lamar 2004 for changes). A wild-caught Common Lancehead (*Bothrops atrox*) fasted for 18 months at Brookfield Zoo (Pawley 1969). The Gladys Porter Zoo was the first to breed this species in the US and Burchfield (1975) provided information for raising neonates. At Dallas Zoo, nine types were maintained and successfully reproduced, including Eyelash Viper (*Bothriechis schlegelii*), Urutu (*Bothrops alternatus*), Coffee Palm Viper (*Bothriechis lateralis*), Jararaca Pintada (*Bothrops neuwiedi*), Black-spectacled Palm Pitviper (*Bothriechis n. nigroviridis),*Yellow-blotched Palm Pitviper (*B. nigroviridis aurifer*), Mexican Pitviper (*Ophryacus melanurus*), Jumping Viper (*Atropoides nummifer*), Mexican Horned Pitviper (*Ophryacus undulatus*), and Godman's Montane Pitviper (*Cerrophidion godmani*) (Murphy and Mitchell 1984). Dunn's Pitviper (*Porthidium dunni*) reproduced at San Antonio Zoo in 2005. Roberts and Hammack (1995) documented reproduction of the Speckled Forest-pitviper (*Bothriopsis taeniata*) at Dallas Zoo.

FIG. 12. John Edwards Holbrook published *North American Herpetology* beginning in 1836, covering all herps found east of the Mississippi River at that time. Shown is Cottonmouth (*Agkistrodon piscivorus*).

Leloup (1975) observed reproduction of Brazilian Lancehead (*Bothrops moojeni*). Kudryavtsev (1985) described the reproductive biology of the Malayan Pitviper (*Calloselasma rhodostoma*) and the Brazilian Lancehead Pitviper (*B. moojeni*) (Kudryavtsev, 1986) in Moscow Zoo. Greene and Campbell (1972) provided notes on the use of caudal lures by arboreal green pit vipers and we saw two species (*Bothriechis bicolor, B. lateralis*) do so at Dallas Zoo. Antonio (1980) described courtship and copulation in Eyelash Vipers (*Bothriechis schlegeli)*. A contribution from Instituto Butantan compared ecological and phylogenetic correlates of feeding habits in Neotropical pitvipers of the genus *Bothrops* (Martins et al. 2002).

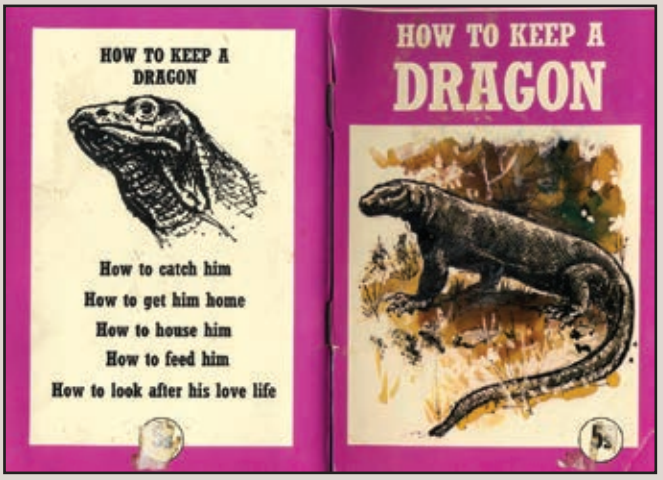
FIG. 13. Habu (*Trimeresurus flavoviridis*, now *Protobothrops flavoviridis*) in *Senchufu* by Tanshu Kurimoto in 1811.

FIG. 14. Illustration of Gila Monster from *Reptiles of the boundary, 1859 / / by Spencer F. Baird ... with notes by the naturalists of the Survey*…The Gila Monster first became known to science in this publication where it was called *Heloderma horridum* and its range was Sonora. Ten years later, E. D. Cope described the species as *Heloderma suspectum*. He chose the epithet "*suspectum*" because he "suspected" it was venomous.

At Dallas Zoo, Card (1994) recorded the natural history and husbandry of the Temple Viper (*Tropidolaemus wagleri*) and Boyer and Roberts (1998) reported on the predatory strike. At the Zoo, an adult lived in an exhibit terrarium, always resting on the same branch. A spider built a web from the upper corner and attached a strand to one of the snake's scales. Each morning, I checked the viper for slightly over six weeks and the web remained unbroken. I surmised that either the spider re-attached the strand in precisely the same spot or the snake did not move; I prefer the latter parsimonious explanation. A Habu (*Protobothrops flavoviridis*) arrived at Dallas Zoo on 15 January 1968 and died on 6 October 1995 (27 years, 8 months, and 21 days) which is beyond the longevity record listed by Snider and Bowler (1992). This snake was always nervous and had to be removed from its exhibit enclosure and kept in the rear section because it discontinued feeding. In fact, the snake was so defensive that the glass-fronted fiberglass cage (with a rear door opening) had to be turned toward the wall so that the human caretakers were not visible to this ophidian (Fig. 13). At Moscow Zoo, Kudryavtsev and Frolov (1984) bred three generations and attempted sex determination of the Bamboo Pit Viper (*Trimeresurus gramineus*). In 2005, 22 Sumatran Pitvipers (*T. sumatranus*) hatched at the Denver Zoo. The Giant or Mang Pitviper (*Ermia* [= *Protobothrops*] *mangshanensis*) reproduced at San Diego Zoo and Gumprecht et al. (2002) provided information on biology, husbandry, and breeding.

There are a growing number of papers on parthenogenesis (asexual reproduction by bisexual species) in pitvipers. Schuett et al. (1997) described this in the Timber Rattlesnake (*Crotalus h. horridus*) and Aruba Island Rattlesnake (*C. unicolor*); Booth and Schuett (2011) provided a table listing reported cases of Long Term Sperm Storage (LTSS) in female pitvipers and other venomous snakes that are suspected to be the result of Facultative Parthenogenesis (FP): Cottonmouth (*Agkistrodon piscivorus*), Copperhead (*A. contortrix*), Mamushi (*Gloydius blomhoffiii*), Long-nosed Tree Snake (*Ahaetulla nasuta*), Mangrove Snake (*Boiga dendrophila*), and Banded Cat-eyed Snake (*Leptodeira annulata*). In this paper, the Eastern Diamondback Rattlesnake (*Crotalus adamanteus*) was added. FP was thought to be an artifact of captivity but recent information has shown that wild-caught Copperheads and Cottonmouths may reproduce in this manner (Booth et al. 2012). Curator Lou Pistoia from Columbus Zoo told me many years ago that a former keeper collected a baby Bamboo Pitviper (*Trimeresurus stejnegeri*) while stationed in Viet Nam during the war, and which was later sent to Pistoia. This snake lived in isolation in a small terrarium and when it matured, gave birth to a living neonate. Naively, I suggested that this phenomenon be published; he countered by saying that this information did not need to be shared with unworthy colleagues.

VENOMOUS LIZARDS



Gila Monsters (Fig. 14) and Beaded Lizards (Fig. 15) have always been prominent zoo exhibits. At Smithsonian National Zoological Park, Demeter (1986) described combat behavior in the Gila Monster (*Heloderma suspectum cinctum*). This behavior is pictured in *Grzimek's Animal Life Encyclopedia* (Hutchins et al. 2003; Beck 2005). At Dallas Zoo, Hartdegen and Chiszar (2001) reported on discrimination of prey-derived chemical cues by the Gila Monster and lack of effect of a putative masking odor. At the same zoo, Garrett et al. (1996) compared chemosensory behavior and prey trail-following in *H. suspectum*.

Anstandig (1983) reported on the breeding and rearing of the Mexican Beaded Lizard (*Heloderma horridum*) and Connors (1993) described the status of the breeding program at the Detroit Zoo, now Detroit Zoological Institute. Honegger (1998) outlined upkeep and breeding in the Zürich Zoo. Peterson (1982) from Houston Zoo and Grow and Branham (1996) at Oklahoma City Zoo reproduced the Gila Monster. Lawler and Wintin (1987) described captive management and propagation of the Reticulated Gila Monster.

Wright et al. (1995) introduced ultrasonographic sexing of helodermatid lizards. Morris and Alberts (1998) and Morris and Henderson (1998) used two-dimensional ultrasound imaging at San Diego Zoo and Lovich and Beaman (2007) chronicled the history of Gila Monster records from California with comments on distribution. Card and Mehaffey (1994) used radiographs to sex Gila Monsters. Espinosa et al. (1996) described a cytogenetic technique for karyotyping Beaded Lizards in Guadalajara Zoo. Morris and Henderson (1998) determined gender in Gila

FIG. 15. Albert Günther was hired at the British Museum in 1857. He was the founder of the *Zoological Record*. This illustration of Beaded Lizard (*Heloderma horridum*, now *H. h. horridum*) is from *Biologia Centrali Americana: Reptilia and Bathrachia* in 1885–1902.

Monsters and Beaded Lizards by ultrasound imaging of the ventral tail at San Diego Zoo. *Heloderma h. charlesbogerti* from the Motagua Valley in Guatemala is critically endangered. When Jon Campbell and I visited the site years ago, it was clear that human-activities would soon place these lizards at risk. This lizard is being bred at Zoo Atlanta; Campbell provided all of the founders. Daniel Beck (2005) has written an excellent book on this group which has relevance for zoo workers.

Jack Cover from National Aquarium in Baltimore was bitten by a Beaded Lizard and sent this account to me (pers. comm., 13 July 2013): "It was late in the day. The guy I worked for at the venom supply company in Baltimore was gone in the afternoon so I was alone—I violated the first rule of working with venomous reptiles—never work with them when alone! I was feeding mice to this lizard but could not find the feeding forceps so I proceeded by feeding him dead mice held by the tip of their tails. The room I was in had a wall phone. The moment the beaded lizard started to lunge at the mouse that phone rang and I looked away to the phone. The lizard went past the mouse and on to my hand—would not let go because he thought he had a mouse in his mouth. Trying to pry the mouth open only encouraged him to clamp down even harder. I walked over to a sink and ran cold water over him (could not do the hot water treatment)—still would not let go. I finally placed him on the floor and when his body contacted the floor he felt secure and released me. Washed out the wound in an attempt to wash out venom. Called the guy I worked for and he called the snake bite doctor at Union Memorial Hospital. I felt no symptoms at this point so I decided to drive to the hospital—second mistake/poor decision. Stuck in rush hour traffic—started to feel a tremendous weight on my chest and systemic symptoms, heart racing. I pulled up in front of my friend's house on the way and got his wife to drive me the rest of the way. Got worse, vomiting and had to be carried into the hospital upon arrival, could not walk. Doctor gave me epinephrine which seemed to clear the symptoms of the serotonin. Went from thinking I was about to die to a quick elimination of all symptoms. What a hands-on experience with the wonders of venom and biochemistry… As an aside, a friend found a Gila Monster nest and eggs in the wild and got very ill from a rodent virus that he got from digging up the nest." At National Zoo, we keep a bottle of the mouthwash Listerine Cool Mint Antiseptic© on hand to spray into the mouth of either species in case they latch on to a keeper's hand; the liquid spray causes them to release their grip immediately.

KOMODO DRAGONS—WHY HERE?

Fry et al. (2009) published a provocative paper from which I quote: "Our multidisciplinary analyses paint a portrait of a complex and sophisticated tooth/venom combined-arsenal killing apparatus in *V. komodoensis* and its extinct close relative *V. priscus*. Thus, despite a relatively weak skull and low bite force, we suggest that the combination of highly and very specifically optimized cranial and dental architecture, together with a capacity to deliver a range of powerful toxins, minimizes prey contact time and allows this versatile predator to access a wide range of prey including large taxa. These results indicate that *V. priscus* was the largest venomous animal to have ever lived." Some researchers urged caution until additional evidence is forthcoming that dragons are venomous (see Weinstein et al. 2012; Weinstein et al. 2013). I recognize that scientific conclusions are provisional and may be subject to change—I am taking the liberty of including this taxon in my paper on venomous reptiles because dragons are kept in zoos and aquariums; these lizards remain one of the most popular for visitors.

Varanids have fascinated herpetologists and herpetoculturists (Fig. 16) for centuries but none more so than the giant of them all—the Komodo Dragon (*Varanus komodoensis*)! Described in 1912 by the Dutchman Peter A. Ouwens, little was

Fig. 17. Photograph by F. W. Wood of Sumbawa standing next to two-year-old child at London Zoo from Joan Procter's article "Dragons that are alive to-day," published in *Wonders of Animal Life* in 1928–1929.

known about this lizard for the next 60 years. Most specimens brought into captivity lived relatively short lives (Murphy and Walsh 2006). The largest one was a male that measured slightly over ten feet at St. Louis Zoo.

Curator of reptiles Joan Beauchamp Procter from London Zoo found that their dragon was unusually tame as discussed in her article "Dragons that are alive to-day," published in *Wonders of Animal Life* in 1928–1929: "The dragon, whose name is Sumbawa, walked around a very long table, and without paying attention to the audience ate a large fowl, several eggs, and a pigeon from her hand, allowing itself to be scratched and patted even when swallowing the fowl with enormous gulps, treatment which even dogs will not always permit." and "She [at death proved to be a male] would tear a pig to pieces but can be trusted with children." (Fig. 17). Procter continued, "The question of the ferocity of these lizards is, perhaps, the most misunderstood of all. All the lizards of the genus *Varanus* are savage, predatory, and highly strung, and they use their teeth, claws and slashing tails with great effect, as I have personal cause to know. At the Zoo we consider any large monitor more dangerous to deal with than a crocodile twice its size. But, allowing for this, *V. komodoensis* is the gentlest, most intelligent, and most tractable of them all. This is comparing them with specimens only half their weight of species such as *niloticus, albigularis, bengalensis, salvator, nebulosus, varius*, and so on. It is quite true that they are very nervous, and also that they could no doubt kill one if they wished, or give a terrible bite when taking food from the hand greedily, but there is no vice in them." Sumbawa was the host at children's tea-parties and was perfectly tame with all the guests. This lizard accompanied Procter on strolls through the Zoo during her inspections, ". . . investigating everything which might be of interest." Amazingly, this lizard responded to the voice of its keeper.

When I visited NZP in 1995, biologist Trooper Walsh asked if I had ever seen a reptile play. I told him that animal play was a controversial issue and many researchers felt that reptiles were just too dumb to do so. He entered an enclosure with a young female dragon named Kraken, approximately 2.5 m in total length and hatched at the Zoo three years earlier. Kraken often exhibited play-like behavior—playing tug of war with a plastic cup, removing pieces of cloth and scarves or notebook from his pocket, scraping his shoes with her forearm, and interacting with empty cardboard boxes. Kraken carried Frisbees, shoes, children's plastic toy action figures, and other objects around in its mouth. Even more remarkably, the lizard stood on its hind legs, directed tongue flicks to Walsh's face, rested its head on his shoulder, and closed its eyes. This lizard stuck its head into a plastic bucket, raised its anterior trunk so that the container covered its head and walked around the exhibit. When Walsh whistled, Kraken turned its head toward the source of the sound. Kraken could discriminate between prey and non-prey. I was flabbergasted and immediately called my friends Gordon Burghardt, the late David Chiszar, and Michael Hutchins and asked if they wanted to do a behavioral inventory and quantitative analysis of these stunning behaviors—see Burghardt et al. (2002). I concluded that there was virtually nothing that a dragon would do that was surprising, other than speaking in a foreign tongue. Trooper and I decided that a lizard that special deserved its own book so we invited our friends Colomba de La Panouse from Thoiry Zoo near Paris and Claudio Ciofi to join us to update Walter Auffenberg's earlier work, *Behavioral Ecology of the Komodo Dragon*, published in 1981. Hence the genesis of our book, *Komodo Dragons: Biology and Conservation*, published in 2002.

Walsh et al. (1993) described history, husbandry, and breeding at Smithsonian National Zoological Park. Pether and Visser (2007) described the first breeding in Europe. The next year, Sunter outlined management and reproduction at London Zoo. Visser et al. (2009) documented the third captive generation at Rotterdam Zoo. Merchant et al. (2012) characterized serum complement activity from specimens at Houston and San Antonio Zoos. Aerobic and anaerobic oral bacteriology of 16 captive dragons at Los Angeles, Honolulu, and Houston zoos was described (Goldstein 2013).

Another surprising finding was that dragons are parthenogenic (Watts et al. 2006). Two females at Chester Zoo and London Zoo produced offspring without male fertilization. Genetic fingerprinting identified parthenogenetic offspring produced by the lizards: "This reproductive plasticity indicates that female Komodo dragons may switch between asexual and sexual reproduction, depending on the availability of a mate—a finding that has implications for the breeding of this threatened species in captivity. Most zoos keep only females, with males being moved between zoos for mating, but perhaps they should be kept together to avoid triggering parthenogenesis and thereby decreasing genetic diversity."

There are many relevant papers discussing exhibition, physiology, and captive maintenance (Aresté 2010; Boyer and Boyer 1997; Boyer et al. 1997; Condie and Monseur 1997; Gillespie et al. 2000; Gyimesi and Burns 2002; Horn 2004; Horn and Visser 1989, 1997; Jones 1965; Lemm et al. 2004; Mendyk 2012; Mendyk et al. 2012; Nijboer et al. 2003; Velensky 2007; Walsh et al. 2004; Wickramanayake et al. 1999; Wiechmann 2012). A wonderful and informative contribution for varanophiles is *Biawak—Journal of Varanid Biology and Husbandry*, an on-line journal edited by Robert Mendyk.

Walsh et al. (1999) discovered that the thermal biology of captive and free ranging wild Komodo Dragons differs, suggesting that captivity is altering thermoregulatory behaviors. There is a strong underlying message here—Komodo Dragons are far more complex than we ever imagined and we may be well be giving them a rather sterile environment that suppresses their normal behaviors and way of life in our zoos and aquariums. The message is that animals in zoos, especially complex ones like dragons, need complex environments that match their abilities.

Conclusion

Zoos and aquariums exhibit many rare species, but sustain few for long periods. Demanding genetic, demographic, and behavioral requirements are a part of the sustainability challenge, and historical zoo goals and limiting animal management objectives are another, but they have been overtaken by worldwide wildlife population contraction and endangerment. New policies are essential for zoo continuance and, if vanishing species are to be helped by zoo propagation, they must be given priority.

However, zoos have little animal carrying capacity and propagation must be much more sharply focused. In addition, it is becoming urgent that zoos help to support parks and reserves and, where possible, manage some especially endangered species mutually with parks.

--William G. Conway (2011)

In the mid-1960s when I entered the zoo profession, there was little discussion about conservation. We chose reptiles and amphibians for the collection, mostly because we liked them, they demonstrated interesting behaviors, and there were plenty of different ones available (see Murphy and McCloud 2010 for examples). Many of our efforts centered on keeping them alive and so we almost never accumulated breeding groups—we could barely sex our animals, much less breed them. Oh, how the world has changed! Today, anyone who does not believe that biodiversity is disappearing at an unprecedented rate must have been living in a hermetically-sealed box for the last several decades. The evidence is overwhelming and the conservation literature is filled with papers documenting this loss and reasons contributing to this wholesale disappearance (e.g., Blaustein and Wake 1990; Blaustein et al. 1994; Brooks et al. 2002; Costello et al. 2013; Gibbons et al. 2000; Lips 2013; Mendelson et al. 2006; Pimm and Raven 2000; Purvis et al. 2000; Rohr and Palmer 2013; Wake 2008; Wake and Vredenburg 2008). This situation is so global in scope—requiring dramatic interventions—that when Ronald R. Swaisgood and James K. Sheppard from San Diego Zoo attended the Society for Conservation Biology meeting in 2009 in Beijing, they warned that most attendees were feeling so hopeless— after hearing each paper more gloomy and depressing than the last—that any positive turn-around was questionable and a continuing culture of despair threatened conservation biology. The usual mantra from the younger people is "What's the use?" These authors suggest that all is not lost and I certainly hope that they are right. I know many biologists and virtually all are pessimistic. Some are now calling themselves "Extinction Biologists," a chilling appellation indeed.

Let me count the ways that some of my herpetological friends and colleagues are skeptical about the long-term success of our *ex situ* zoo conservation projects. Ecologists and evolutionary biologists tell me that extinction is part of the natural mosaic—I need to deal with it, get over the loss of biodiversity and give up intervening—I should just trim my fingernails indifferently and watch it happen. Academic and museum scientists tell me that successful reintroduction is unlikely since there are virtually no suitable places likely to be left after man has intruded into the habitats. Even if some relatively pristine protected areas can be found, the bureaucracy of getting permission to release captive-bred offspring is daunting. Besides that, our captive animals have been shaped in a negative way by becoming domesticated, as pointed out by the late Henry Fitch in 1980. There are few careful studies that assess the competence of our propagules. My colleagues ask me that if our captive animals are competent, then why do we need to resort to procedures like assisted reproduction? The possibility of introducing infectious disease harbored by captive animals is always a concern. Some conservation biologists tell me that we should produce as many animals as possible, related and unrelated, dump them into a secure place and let natural selection weed out the unfit. They point out that genetic diversity is not the only measure of success for survival. Others say that we should not bother with captive assurance colonies at all but rather spend our money buying land focused on endemic hotspots and hiring armed guards to protect them. A few say we should only set up breeding colonies in countries of origin. Some of my fellow zoo professionals say that many captive colonies have proven to be wasteful in terms of resources and unsustainable. They point out that some species coordinators take a long period of time to send recommendations to minimize inbreeding depression, that others do not send updated information or respond to the recommended pairings, that shipping costs are skyrocketing, paperwork to transfer animals between zoos is dramatically increasing, and there are not enough founders to sustain many populations over the long haul. Although we may try to deal with the founder issue, many countries are loathe to approve sending animals collected from the wild to zoos and so the requisite paperwork needed to do animal shipments is not issued. Registrars have witnessed a dramatic change in that fewer live animals are shipped now and requests for shipping biological materials have increased exponentially. Is it any wonder that zoo biologists are uncertain about their future role in conservation, especially when criticism and suggestions for improvement—often contradictory—comes from many different directions?

Card et al. (1998) asked an important question—does zoo herpetology have a future? Do we want to be major players in conservation and, if so, where should we marshal our very limited resources of time, space, and money to protect animals at risk? At American Association of Zoos and Aquariums (AZA) meetings in the herp Taxon Advisory Group (TAG) sessions, the reality of putting breeding plans in place to cover amphibians and reptiles in danger of extinction is staggering—there are simply too many species in jeopardy and not enough space in captivity. When I talk with zoo people working with endangered mammals, birds, fishes and invertebrates, it is clear that their experiences parallel ours. We are fighting with each other for a bigger piece of the conservation pie (and that pie is shrinking). Which animal is more important to save—Asian Elephants or Aruba Island Rattlesnakes? And most crucially, is there a realistic chance of success? Are our assurance colonies going to be nothing more than assisted living complexes? If assurance colonies are the end point, then why do we bother? Perhaps the programs and colonies exist only to have animals available for our institutions in the future without the slightest hope of reintroducing them? If this is our purpose, we should say so and not advance the notion that this is conservation. How about a middle ground where we do the assurance colonies with the best outcome being reintroduction and the worst being only in zoos and the middle being 'should conditions in the wild merit it, animals would be available for reintroduction.'

I am confused about all the talk about reintroduction espoused by the zoo community. If a taxon is at risk in the wild, the prime reason seems to be that human activities have changed its living space in some fashion. There are many examples: strip-mining, mountaintop removal, introduction of invasive species,

FIG. 18. Art Lopez, Jerry Rutledge, and the incomparable Barry Armstrong (left to right) on a collecting trip to Mexico in 1974.

PHOTO COURTESY OF WILLIAM W. LAMAR/GREENTRACKS

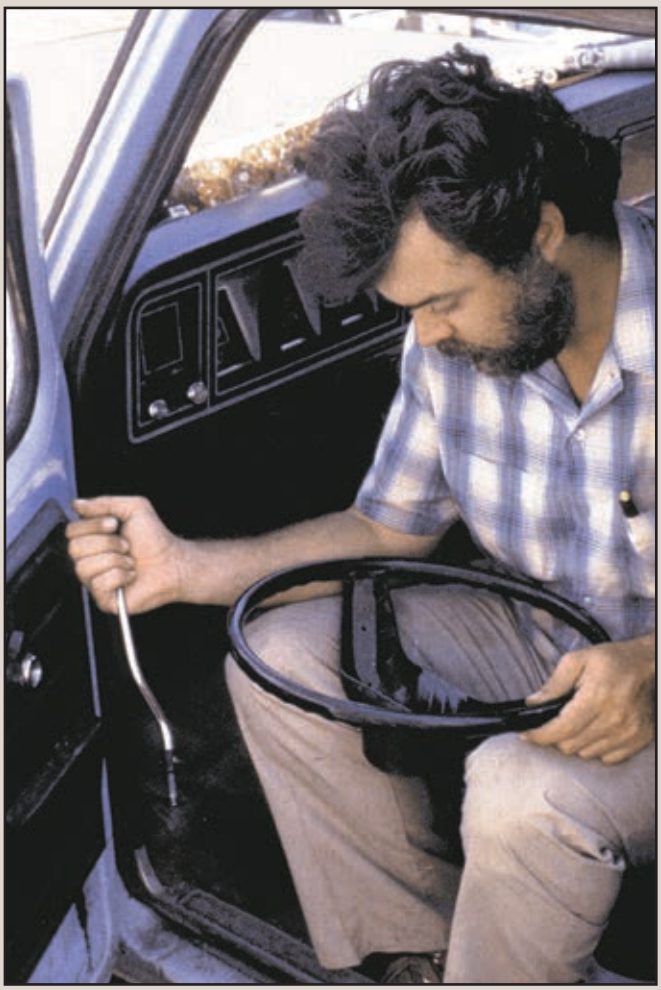

FIG. 19. Jonathan A. Campbell surveying a setback on a collecting trip at Comitan, Chiapas, Mexico. The steering wheel and gear shift fell off as they were driving on a treacherous mountain road in Chiapas. During another trip traveling through Mexico City, Campbell and Barry Armstrong were given a ticket for having a pick-up truck that was too dirty—they were livid at this blatant shakedown. This truck (Ford Ranger F150 Pickup) was called "Blue Goose" and had over 300,000 miles on the odometer, until it was sold to a used car dealer for US $25.

housing developments, oil exploration, clear-cutting forests, water pollution and others equally damaging. If those activities continue, then surely it is illogical to even consider putting captive animals at risk back in original habitat. As I see it, the only other option is reclamation after developers have had their way destroying the land. Studies are needed before the land is ravaged and thought as to what it takes to bring it back or can it even be brought back to its original state. So do we redirect funds to support reclaiming ravaged lands and make this our highest priority?

Scott Pfaff from Riverbanks Zoo told me that he contacted 40 zoos about a decade ago to help develop a breeding program for King Cobras as a way of ensuring that these spectacular snakes would always be available in the future. To do this, a zoo would have to commit to maintaining breeding pairs, incubating eggs, raising neonates, and distributing snakes to other institutions. Only two institutions were willing to participate and most of the others wanted only one large adult for display, expecting Scott to raise their snake until it was large enough for that purpose. Reminds me of the old folk tale: "Who will help me bake the cake?" asked the *Little Red Hen*; "Not I, not I," said all the other animals in the barnyard. "Who will help me eat the cake?" "I will, I will."

Again, I quote William Conway: "Successful specialized propagation programs for bats, beetles, snakes, and fish underscore the point: *Specialization is key to every successful threatened species propagation program."* I here propose a plan for future captive populations in our zoos and aquariums using the Conway model as a guide. In a true Darwinian sense where species are selected against if unfit, we should ruthlessly evaluate all of our current programs, using the Aruba Island Rattlesnake (*Crotalus unicolor*) initiative as a model that includes placement on the *2007 IUCN Red List of Threatened Species, Population and Habitat Viability Analysis, Species Survival Plan* and papers on the project (Odum and Goode 1994; Odum 2010). For new ones, we should insist that an *in situ* component be required—this could include sending money to support scientific studies such as infectious disease, setting up rehabilitation and breeding centers for eventual release, training students and wildlife officials, rebuilding productive collaborations and interactions among the zoo, academic, and conservation biologists, actualizing a plan for public education, developing recommendations for protecting habitats and creating reserves, and a host of other challenges requiring our help. For those now existing without this element, we should consider requiring addition of an in-country plan and if this is not possible, letting them leave the collection through attrition. We must always ask the critical question: are our plans in place consistent with intended results and if not, are we willing to jettison them and try something different?

Conde et al. (2011) recommend a plan that is tangential to mine or even bolsters the idea that species should be ranked: "Because ex situ conservation programs can be challenged when called into action at the last possible moment with only a few remaining individuals of a species, captive breeding should not be simply seen as 'emergency-room treatment.' It is a tool that should be considered before the species has reached the point of no return."

Now that I think of it, perhaps all the discussions taking place—of rewilding and de-extinction and forensic taxonomy—are a measure of just how desperate everyone is feeling. My friend Joe Mendelson sums it up succinctly (2011). Well, we certainly have much to discuss as captive managers and zoo/aquarium conservation biologists and we do not have much time to get it right!

Acknowledgments.—This paper is dedicated to Barry L. Armstrong (Fig. 18) and Jonathan A. Campbell (Fig. 19). When the Pierre A. Fontaine Bird and Reptile Building at Dallas Zoo opened in 1966, the collection was unimpressive and of little interest to academic, museum, and zoo herpetologists; very few of them bothered to stop by to see our charges. About a decade later, Barry and Jon started to go down to Mexico and Central America to collect amphibians and reptiles, based in large part on Campbell's need to have a comprehensive assemblage for his doctoral dissertation. These intrepid explorers were extraordinarily successful at finding rare and unique herps but many were not immediately preserved. To ensure that these living creatures were not left in bags and jars for weeks at a time, they undertook several trips from the collecting sites back to Dallas each year and placed them on loan at our zoo.

Before each trip, we would gather at my home in Dallas and generate desiderata for what might be collected. There were two camps—Campbell and Armstrong who claimed that they would succeed where others failed versus Murphy who stated emphatically that their goals were too lofty and unattainable. The reason for this was to create wagers—the loser(s) had to underwrite the cost of a lobster–steak dinner, amply supplied with libations, at a five-star restaurant. The winner(s) would bask in glory with credit card receipt unsigned and wallet intact!

These sessions were remindful of draft day for a professional football conference as lists were developed and players chosen; our interactions became somewhat heated as the night wore on—we were ethanol-fueled—and we vigorously jockeyed for position to put the other side at a disadvantage. Finally, after much wrangling, we completed the final list and had to live with the results. Campbell claims to this day that he and Barry were the clear winners although I believe that results were about equal. Even if results were equal, I still lost ground because there were two of them and only one of me—they had prodigious appetites!

There is no question in my mind that as our collection began to gain international recognition and herpetologists throughout the world began to regularly visit us, my two friends were the primary reason for our success and I will always be grateful to them.

Thanks are due to Kraig Adler, Randal Berry, Judith Block, Jon Campbell, Brian Gratwicke, Ken Kawata, William Lamar, Karen Lips, Stephen Mackessy, Joe Mendelson, Robert Mendyk, Scott Pfaff, and RDC staff (Lauren Augustine, Matt Evans, and Matt Neff) for reviewing early drafts. Leslie K. Overstreet, Curator of Natural-History Rare Books, Smithsonian Institution Libraries, has been extremely helpful in assisting with historical information. Librarian Daria Wingreen, in SI Special Collections Department, and Erin Rushing, Permissions Coordinator from the SI Libraries assisted me in duplicating images. Librarian Polly Lasker arranged for photocopies of pertinent publications and provided background information.

Over many years, I have had fruitful discussions with these persons about the role of zoos and future challenges: Colette Adams, Kraig Adler, Fred Antonio, Barry Armstrong, James Bacon, Dave Ball, Chris Banks, Dave Barker, Ben Beck, Charles Beck, John Behler, Randal Berry, Dave Blody, Quentin Bloxam, Don Boyer, Bill Branch, Ed Bronikowski, Kevin Buley, Pat Burchfield, Gordon Burghardt, Jonathan Campbell, Winston Card, David Chiszar, Joe Collins, Roger Conant, Jon Coote, Jack Cover, Béla Demeter, Scott Derrickson, Jeff Ettling, Gary Ferguson, Jack Frazier, Ron Gagliardo, Carl Gans, Clay Garrett, Janis Gerrits, Richard Gibson, Ron Goellner, Brian Gratwicke, Harry Greene, David Grow, Robert Hansen, Gene Hartz, Ron Heyer, Rick Hudson, Tom Huff, Howard Hunt, Michael Hutchins, Warren Iliff, Jeremy Jackson, Elliott Jacobson, Ron Kagan, Alan Kardon, Ken Kawata, Dennis Kelly, Dan Keyler, Sergey Kudryavstev, Bill Lamoreaux, Michael Lannoo, Joe Laszlo, Dwight Lawson, Bill Lamar, Karen Lips, Sergey Mamet, Dale Marcellini, Ed Maruska, Ken McCloud, Roy McDiarmid, Bill McMahan, Joe Mendelson, Don Middaugh, Don Moore, Andy Odum, Ray Pawley, Marlin Perkins, Scott Pfaff, George Rabb, Charles Radcliffe, Dave Roberts, Richard Ross, Steve Sarro, Robin Saunders, Dave Schleser, Frank Slavens, Brandie Smith, Ed Smith, Hobart Smith, Peter Tolson, Bern Tryon, Gerard Visser, Trooper Walsh, David Warrell, Barbara Watkins, Paul Weldon, Judy White, William Xanten, Kevin Zippel, and George Zug. I am grateful to all for stretching my brain.

How Snakes Work: Structure, Function, and Behavior of the World's Snakes

Harvey B. Lillywhite. 2014. Oxford University Press, New York (http://global.oup.com). Hardcover. xiii + 241 pp. US $49.95. ISBN 978-0-19538037-8.

DAVID CUNDALL
Biological Sciences, Lehigh University, 1 W. Packer Ave, Bethlehem, Pennsylvania 18015-3001, USA
e-mail: dlc0@Lehigh.edu

Randomly flipping open Harvey Lillywhite's new book is likely to land you on one or more fascinating photos or figures. If you are like me, that will begin an exploration of a topic that will have you flipping back and forth through this book to see what Harvey has to say about skin color, or egg form and size, or predator-prey interactions, or any one of innumerable questions that snake enthusiasts think about. As a physiologist with a broad spectrum of interests focused on snakes, Harvey has done serious scientific work on an amazing variety of questions. To communicate his interests and findings to the general public, he has devoted a lot of energy to finding excellent photos or drawings that encapsulate concepts or processes and their structural foundations.

Harvey Lillywhite has managed to convert his scientific prose from many publications into readable and entertaining explanations. The book is profusely illustrated in color, mostly with previously unpublished photos and illustrations by the author, his students, and a host of colleagues. Since this is a review for herpetologists, I'll comment on what I regard as the scientific value of the various parts of the book — and on some of its scientific weaknesses. Because Lillywhite's expertise in many aspects of the physiology of snakes is probably unparalleled, my criticisms focus primarily on those parts of the book with which I have experience.

The book has a foreword by Rick Shine, a brief preface explaining Lillywhite's goals in writing the book, acknowledgments, nine chapters, each with its own selected bibliography, a glossary, and a useful index of taxa and terms. Given the number of popular books on snakes, one might ask whether this book provides anything new. The pithy title turns out to be accurate. The only books I'm aware of that come close to this are Parker's (1965) little book (revised by Grandison, 1977) and Bellairs' two volumes on Reptiles (1970). Ernst and Zug's (1996) volume *Snakes in Question* covers some of the same topics and questions but not in the coherent manner of Lillywhite's book.

The book begins with a brief survey of snake diversity and Lillywhite's current view on snake relationships drawn primarily from recent molecular studies. As with all the following chapters, it begins with a quote, this one from Malcolm Smith's (1943) book on Indian snakes noting the importance of natural history in interpreting structure, function, and phylogeny. To emphasize the potential rigors of meeting this demand, among the many photos of henophidian snakes is a large photo of Jesus Rivas and a friend carrying what looks like a 6-m anaconda. It accompanies neat photos of *Anomochilus monticola*, *Anilius scytale*, a vertebra of *Titanoboa*, and others. Abundant photos of other representative species show the diversity of habitats that snakes have successfully occupied and the diversity of head and body shapes and colors that snakes have evolved. It ends with a cladogram drawn largely from recent molecular analyses that provides the framework for discussions in the rest of the volume. Although many readers may not be interested in the evolutionary relationships of major snake clades, the inclusion of the cladogram could have provided an opportunity to comment on the fact that recent morphological (Gauthier et al. 2012—not cited) and molecular analyses (Pyron et al. 2013—cited) of snake phylogeny are raising important questions about how both sets of characters evolve.

The second chapter covers the physiological aspects of nutrient acquisition—feeding, digestion, and water balance. It starts by noting the major constraints acting on snakes, reminding the reader that snakes are basically animated tubes with a head at one end and a tail at the other. The explanations of how different snakes eat include some descriptions of kinetic skulls in henophidian and colubroid snakes and briefly mentions some of the structural foundations of jaw kinesis. Specialized feeding mechanisms, like mandibular raking in leptotyphlopids, and mandibular transport in snail eaters, are also explained, with credit given to Nate Kley and Beth Brainerd for figuring out the remarkable characteristics of the former. The chapter covers almost all aspects of feeding in snakes, including specializations for restraining prey, venoms and venom delivery systems, digestion and digestive adaptations including beautiful micrographs of stomach and intestinal histology from Jacobson (2007), and sequential x-ray images of a barium-injected chick being digested by a rat snake. It ends with the roles of skin, kidneys, and salt glands in maintaining water balance and with the basic mechanisms of drinking.

Locomotion, the subject of the third chapter, begins by noting the relationship among vertebral number, speed of locomotion, and body form. Skeletal and muscular features are described with the aid of photos of vertebrae and ribs and neat dissections of body segments that make clear the extraordinary length of tendons and some of the complexity of muscle arrangements. However, the photos will also make clear to those who actually know some anatomy why photos are poor substitutes

for good drawings. Sea snakes and swimming are treated first along with some of the experimental approaches to testing relationships between the form and function of swimming snakes. This leads into a brief treatment of terrestrial locomotion and the limited studies of how snakes generate the forces necessary for locomotion, apparently done at human generational intervals (about every 30–40 years). The rest of the chapter focuses on the different kinds of locomotory movements that snakes use and how these relate to the environment, and ends with a brief introduction to snakebots, the use of engineering methods to create robots that move like snakes and also make clear some of the basic functional and structural demands operating on snake-like locomotion.

The next chapter deals with temperature and is introduced with a quote from Michael Angilletta's 2009 book and a photo of a *Crotalus durissus* with arrows and labels showing the various routes and types of heat flow to and from the snake. After explaining in very general terms how heat influences metabolism and molecular structure and function, and how snake bodies limit the kinds of behaviors snakes can use for thermoregulation, we learn about the types of physiological studies that have been done to understand thermal relationships of snakes. Lillywhite discusses both field and laboratory studies and rightly notes the limitations of our current data. He also considers the difficulties entailed in measuring some of the factors influencing regional differences in temperature within snake bodies and responses to temperature extremes. Evidence for thermogenesis during egg incubation in pythons and in colubrids exposed to extreme cooling (below 2–4ºC) is given along with a review of the many studies on heat and cold tolerance and the effects of temperature on activity.

How snakes exchange things between themselves and their environments is really the fundamental theme of the book but Lillywhite has sensibly not focused on all the quantitative physiological aspects of the issue. After discussing heat exchange, and intimating frequently that the skin plays a role, he gets down to explaining exactly how the skin does this in snakes in Chapter Five. As in the other chapters, the basic structure of the skin is introduced first with excellent micrographs by Jacobson (2007). The chapter goes on to explore the basis of color and patterns and how the potential functions of the skin in mimicry and defense have been experimentally tested. A short section on color acquisition from the environment deals primarily with soil adherence in some species like Cottonmouths (*Agkistrodon piscivorus*). A longer section on the genetics of coloration doesn't actually deal with any genetics but describes various polymorphisms, with three color morphs of *Lampropeltis californiae* shown but only one color morph of *Python brongersmai* shown and none of *P. regius*, the species that appears to be the current craze among snake color morph fanciers for its extraordinary range of colors and patterns.

Given Lillywhite's many publications on vascular function in snakes, I was looking forward to his synthesis of how circulatory and respiratory systems of snakes work. Getting into the chapter involved delving through the basics of circulatory system design and terminology written in a style that seems suitable for elementary school students. The anatomy of the snake heart and how its form allows shunting between pulmonary and systemic outflows is covered with some interesting details and then the chapter progresses to vessel patterns and hemodynamics. Lillywhite discusses at length how the design of the snake body should generate major potential problems in hemodynamics due to gravity in terrestrial environments, using sea snakes to show how blood pools in the lower part of the body if the snake is held vertically by its head. Holding terrestrial species in this manner rarely results in changes as observable as those in sea snakes, and Lillywhite comments on some aspects of vascular design that permit maintenance of blood flow to the head regardless of body position in climbing snakes. The last half of the chapter introduces lungs with some photos of fresh lungs, including tracheal lungs, and an excellent micrograph of a resting, uninflated lung, again from Jacobson (2007). The basics of gas transport are developed and the functions of both vascular and non-vascular regions of the respiratory tract (saccular lung, tracheal air sacs) discussed. Numbers appear intermittently to make points—blood pressure values and lung faveolar spacing in various species, but how these fit into a form/function argument are not elaborated. Lillywhite fittingly ends the chapter exhorting readers to contemplate all the unanswered questions about how different snakes may have resolved cardiovascular and respiratory demands.

Perceiving the snake's world, the next chapter, leads into an area about which I have long accepted that I know very little. Inasmuch as my perception of most things differs from my wife's, understanding what a snake perceives has always been to me the equivalent of a leap into an abyss. Others do not accept my view, and they have forged ahead on trying to understand sense organs in snakes. Lillywhite summarizes the years of research on snake sense organs with illustrations of the superficial aspects of the organs only. However, he covers what we know of the physiology of those organs and the correlations with behavioral changes. The many experimental tests on infrared sensing, vomerolfaction, hearing, and tactile receptors combine to show that snakes do sense an extraordinary range of environmental stimuli but how these all lead to 'perception' remains, to me, a puzzle. Lillywhite ends the chapter with "…perhaps our perception of the world around us is not really that different from that of a snake. Think about this." I have, and I have reached a different conclusion.

Anyone who has kept Puff Adders or rattlesnakes knows that some snakes are noisy. Lillywhite must have puzzled over this like many of us. Sound production in snakes amazingly gets a whole chapter devoted to the careful scientific studies by relatively few people, most notably Bruce Young and his teams of students. I can understand Lillywhite's dilemma in conveying the scientific problems involved in rattles, hisses, growlings, and poppings without the physics of acoustics. He manages to cover both the range of sounds made by snakes and the various structures that produce the sounds, but unlike all the other chapters, this one doesn't benefit much from its figures. Reference to some of the excellent photos two chapters previously help to explain the respiratory associated sound-producing structures. However, the photo of an *Echis* doesn't show the scales responsible for sound production clearly and a later photo of the skin of a seasnake is presented without any reference to sound. I was unable to figure out where the circumferential ridges are on the photo of the Gaboon Viper external naris.

The last chapter of the book deals with courtship and reproduction. The "essentials" of reproduction follow a short section on the mythology of snakes and their relationship to various human cultures. After commenting briefly on generations of individuals (here referred to as G_1 and G_2 -instead of the more familiar F_1 and F_2 generations) and the transmission of genetic information as DNA, there is a similarly brief explanation of how

to tell male from female snakes by probing. The description suggests that the probe actually enters a pocket housing the hemipenis, rather than entering the inverted hemipenis itself. Tail is somewhat confusingly misspelled as 'tale' several times in this section. The claim is made that the erected hemipenis is inserted into the cloaca or vagina. I have always assumed, having admittedly watched relatively few mating events, that the hemipenis everted into the cloaca while the vents of the mating pair were pressed together, and I've always wondered how the male regulates which side is everted. Gonads are introduced, and a real puzzle, how sperm get from the ductus deferens (not mentioned) to the sulcus spermaticus of the hemipenis, is not mentioned, possibly because no one has figured it out. Oviparity and viviparity are compared from physiological and environmental perspectives. Egg laying and the attendance and incubation of eggs are reviewed as is the limited available evidence on parental care of neonates. Growth patterns, sexual maturation, and survivorship are all considered although the difficulties of measuring energy flow in natural populations, and the efforts to do it, are not included.

The book is not without its problems and errors. Some of these should have been averted by competent editing prior to publication. Others are clearly the author's responsibility. In a figure showing three frames of a striking *Corallus hortulanus* recorded by Phil Nicodemo, propulsive and reaction forces, and their explanations in the legend, seem reversed and the legend ends with "the head moves forward to bite forcefully and immobilize the prey." After recording over 2000 strikes from about 50 species of boas and pythons, Fran Irish and I can attest that mammals bitten by snakes, even long-toothed *Corallus* or *Morelia*, are rarely if ever immobilized by the bite. Immobilization is the result of death by constriction. One egregious error involves a finding attributed to me. In the feeding chapter, I am cited as saying that "up to 47% of rattlesnake strikes result in neither fang penetrating the prey." What I actually wrote (2002) was "Among the strikes recorded by me, 19/88 (22%) were flawed in some respect and 9/19 (47%) resulted in no fang penetration at all." In other words, almost half the flawed strikes but only 10% of all strikes result in no fang penetration. In a later paper (2009—not cited) based on about 10 times as many strikes, I provided a better estimate of how frequently vipers reposition one or both fangs during a predatory strike, estimates supported by data previously published by Young et al. (2001) for a single species of rattlesnake.

As an anatomist, I was disappointed to see a surprising number of errors in presenting aspects of snake anatomy. In Fig. 2.2, carotid is misspelled (cartotid). Drawings of a lizard and a snake skull (Fig. 2.4) will astound anyone with a basic knowledge of skeletal anatomy in vertebrates. The ostensible reason for the drawing was to show lizard and snake modifications of the diapsid condition, but sutures are randomly included and show bone arrangements unknown in any lizard or snake (Evans 2008; Cundall and Irish 2008). Figure 2.7 supposedly shows a sequence of jaw movements in a king snake (*Lampropeltis californiae*) swallowing a mouse, but the jaws cannot be seen, and the caption ends by noting that "the mouse is positioned within a loose coil of the snake, thereby 'anchoring' the prey so that it does not shift away from the snake during advances of the jaws." …a statement that seems to ignore the fundamental ratchet properties of the pterygoid walk. Figure 2.21, a drawing of tooth implantation in snakes, shows aspects of a lizard pleurodont condition but with no alveolar socket, a much higher labial pleura than is found in most alethinophidian snakes, and ligaments rather than bone of attachment connecting the base of the tooth to the tooth bearing element (Zaher and Rieppel 1999). As noted by Savitzky (1981), only a few hinged-toothed snakes retain ligamentous tooth attachment. Figure 2.27, another drawing, this one copied from Kardong (2006, also 2009), converted what was originally the quadratomaxillary ligament into what appears to be a new bone in front of the quadrate and lying over the venom gland compressor. The intestine is described has having villi (p. 65) despite the fact that Parsons and Cameron (1977) and Luppa (1977) both reviewed snake intestinal anatomy and showed that the small intestines of most snakes lack villi. Even more surprisingly, nutrient absorption from the gut is claimed to take place primarily in the large intestine (p. 65).

Other minor errors abound. The snake heart is claimed to have a "valved interaortic foramen" (p. 143), a structure I cannot find described anywhere, although crocodilians do have a foramen between the left and right systemic arteries, the foramen of Panizza. Perhaps interaortic foramen refers to the space between the ventricular septum and the entries to the systemic and pulmonary arteries? The chapter cites Wallach's (1999) chapter on snake lungs but includes no citations or mention of other chapters in the same volume that review the structure and function of the heart in snakes. The chapter on reproduction contains a figure (9.10) copied from Blackburn and Stewart (2011; not Stewart and Brasch 2003, as stated in the caption) showing placental types in snakes—but done without color so that the vascular nature of the extraembryonic yolk sac and allantois are not clear or labeled. Worse, none of the extraembryonic membranes are shown as having any connection to the embryo—an unfortunate feature of the original drawing and one that makes it unclear as to how anything could be transported between these membranes and the embryo.

The focus of the book is on how things work, not how they are built. Lillywhite has done an excellent job of showing where we are in understanding how things work. However, forging ahead on most of the "how they work" questions is likely to require a much better understanding of how they are built. Lillywhite tacitly acknowledges this by explaining relevant structures in every chapter. In almost all cases, the anatomy could have been developed more carefully and with better illustrations.

The book's cover says "written for both professionals and a more general audience," but trying to satisfy both groups is a serious challenge. Much of the writing is clearly intended for a "general" audience. Not being a publisher, I do not know how a general audience is defined, but I assume it is people not trained in science beyond the high school level. Some parts of the book actually seem to be targeting an audience with no science education at all, but the treatment of snake examples suggests it is intended for the amateur herper. I'm not sure, however, that the amateur herpers of today are like those at the time when Harvey Lillywhite and I were both amateur herpers ourselves. Having spent years going to the local Hambug, Pennsylvania, "herp expo," I have watched a change in the nature of both the types of people attending and the nature of items for sale. What are no longer for sale are books, a change that has occurred just in the last few years. Unlike the bibliophilic amateur herpers of old, the current crowd is apparently not a book-buying population.

In summary, I like the book despite its shortcomings. What Lillywhite has given us is a summary of his life's work and interests. I think he has succeeded in showing both what he and colleagues have discovered and why snakes deserve a lot more

research—including research on the foundations of function, namely, anatomy. He ends the book with a plea to readers to encourage others to appreciate snakes … and the rest of the natural world. One can only hope that the book will be an unbridled commercial success—both to support his plea, and possibly to justify a second edition with a little more polish.

When presented with a lizard or frog that eludes immediate identification, the first reference for many, interested amateur and professional herpetologist alike, is a field guide. For North American taxa, that usually means referring to the Peterson Field Guides, either Conant and Collins (1998) or Stebbins (2003). However, as field guides are specifically geared toward identification of living individuals and tend to emphasize color pattern, specific identification of preserved specimens often proves impossible, and even live animals can be troublesome to identify when "off-color" due to physiological changes, an approaching skin shed, or other factors. In these cases, identification keys prove their worth. Since 1998 the standard general key to the herpetofauna of North America has been Robert Powell, Joseph Collins, and Errol Hooper's First Edition *Key to the Herpetofauna of the Continental United States and Canada*. Now, a revised and updated second edition, released in 2012, admirably fills the role of comprehensive North American key. Much of the text in the Second Edition is identical to the First Edition; nonetheless this update is sorely needed. As stated in the Second Edition's introduction, coverage of native taxa has increased from 545 to 634 species, while coverage of alien taxa has risen from 39 to 58. In addition to an increase in the number of covered species, there are two other significant changes present in the new edition. Range maps have been contributed by Travis Taggart and are included for select sets of species, and taxon-specific commentary has been significantly expanded, most of which highlights areas of taxonomic disagreement or uncertainty and provides references to the relevant literature in each case.

For readers unfamiliar with the current or earlier edition, the product is exactly as advertised on the cover: the vast majority of pages in the book are devoted to a dichotomous key to the reptiles and amphibians of North America north of Mexico. The key itself is preceded by a short introductory section and followed by a glossary and the literature cited. The four-page introductory section (actually an "Introduction to the Second Edition" and "A Word to Users of This Key," plus acknowledgments and a list of

abbreviations), while short, accomplishes several things. It defines the intended core audience: college-level herpetology students. It defines the taxonomy followed in the key (Collins and Taggart 2009), which may seem trivial, but is not. It defines the intended scope of the key, which is written to allow one to identify an adult individual of every species of amphibian and reptile with established populations in North America north of Mexico. Finally, it includes the admonition that not all specimens can be successfully identified with a key alone, a truism many of us have experienced firsthand.

The heart of the book is of course the 134 pages of dichotomous keys. For any such key, authors must make structural decisions that can ultimately affect utility to particular audiences. What taxa should be included? Should arrangement favor diagnostic simplicity and grouping of phenetic clusters, or should taxonomy rule the day? What types of characters should be used? Powell et al. have made reasonable decisions in all these areas. Upon receiving my copy of the book, I went through several cycles of "I wonder if the authors included *this* species?" Invariably, the answer was yes, whether it was the continental United States' only amphibian listed by the IUCN as extinct (*Plethodon ainsworthi*) or the latest exotic species established in Florida. Even some exotic species that have been reported but have not established populations are mentioned, such as Anacondas (*Eunectes*), though such species are not included in the key. It should be noted that coverage extends only to the species level, and each species receives a single terminal entry, which is generally not problematic but can result in unwieldy couplets when one species is polytypic, a prime example being the couplet differentiating *Ensatina eschscholtzii* from *E. klauberi*. Though each species is associated with a single terminal entry, inner reticulation is used where appropriate, so that, for instance, multiple roads lead to *Lampropeltis*. This allows for a reasonable compromise between producing an idealized diagnostic key versus producing an idealized synoptic key: members of the same genus or family are always grouped together, but by not forcing a single entry to lead to a particular family or genus; concise, easy-to-follow diagnoses are maintained for internal couplets.

Powell et al. have not restricted themselves in the classes of data used to characterize sets of taxa. The major exception is internal anatomy, which is avoided, though characters requiring observation of the inside of the mouth (tooth rows and counts, presence of choanae, tongue shape and attachment site) are used regularly for amphibians, and acrodont tooth attachment is used as the distinguishing trait for Agamidae. Most entries in the key stress external anatomy, however, with geography and color pattern also being important. Occasionally, other classes of distinguishing characteristics are also included where appropriate (e.g., acoustic and karyotypic information for *Hyla chrysosceles* and *H. versicolor*). When color pattern is used, the authors are also careful to note pattern elements that tend to fade in preservative (such as the yellow thigh markings of *Hyla avivoca*). Terminal entries for species also include referrals to each species' accounts and illustrations in Conant and Collins (1998) and/or Stebbins (2003), along with accounts from the *Catalogue of American Amphibians and Reptiles*, if available.

Important morphological characteristics and geographic ranges are illustrated through the use of 279 line drawings and 25 maps. While a few of the maps depict the range of only a single species, most serve to illustrate range differences among members of a species complex. Maps (sometimes two) are included for all the well-known troublesome species complexes: slimy salamanders (*Plethodon* spp.), southwestern leopard frogs (*Lithobates* spp.), Gulf Coast drainage map turtles (*Graptemys* spp.), fence lizards (*Sceloporus* spp.), and kingsnakes (*Lampropeltis* spp.), among others. These prove their worth, especially when, as in the slimy salamanders, identification to species level is impossible based on external morphology alone. Even more so than the maps, the line drawings are exceptional. They are, in fact, my favorite aspect of the entire book. Significant morphological features are illustrated with a level of detail and precision that is difficult to depict in a photograph or field guide illustration. Coupled with captions describing the relevant features, the result is that written descriptions that have the potential to confuse instead enlighten, so that a user of the key need not wonder just how big an enlarged preanal scale is supposed to be, or what a gular crest looks like. Especially notable are the head and body drawings that appear at the start of sections for each major herpetofaunal group, which identify features such as types of head scales in lizards and snakes (oculars, gulars, labials, etc.) or dorsolateral folds in frogs. The identity of these structures is second nature to most professional herpetologists, but can be a source of confusion to non-specialists.

Following the key itself are 14 pages of glossary and literature cited, which together complete the book. The glossary, which spans four of these pages, is exhaustive and as far as I can tell includes entries for all but the most basic of anatomical terms used in the key. For example, while "hand" does not get an entry, "claw" does. Directional terms (distal, dorsal, etc.) are given entries in addition to the many entries describing various anatomical structures. There are also a few non-anatomical terms defined in the glossary (e.g., *sensu lato*). The literature cited is complete, and is actually a good starting point if one were interested in synthesizing the literature on recent taxonomic changes and uncertainty affecting the North American herpetofauna. In this respect, it serves as a reminder of the work done by the late Joseph Collins through the Center for North American Herpetology to disseminate our ever-changing conception of North American herpetofaunal diversity.

There are some features not included in the book, two of which in my opinion would significantly increase its utility. First, the Table of Contents only lists taxa down to the family level, and the book has no index or other comprehensive list of included genera and species. One might think that this list exists outside the book in the form of Collins and Taggart (2009), but that would be inaccurate. Powell et al. did not limit their coverage to species recognized up to 2009, so that there are species in the book than are not listed by Collins and Taggart (2009), and there is no easy way to determine which additional species have been added. For example, among turtles only by paging through entries can one determine that *Graptemys sabinensis* gets its own entry while *Kinosternon steindachneri* does not. In addition, the lack of a numbered taxonomic index makes it more difficult to work backwards in the key from a set of potential species as a means of identifying diagnostic features.

The second major omission is the lack of identification keys for larval amphibians. This significantly cuts into the comprehensiveness of the key, and is especially problematic for salamanders. The decision not to include salamander larvae results in the erection of an artificial morphological distinction between these and the adults of related paedomorphic species. This has a strong potential to lead to misidentifications of aquatic, gilled salamanders. The authors do briefly state their non-inclusion of larval keys in their introductory word to users, but do not

suggest alternatives for larval salamanders or tadpoles. Although becoming dated in nomenclature and species content, such resources do exist, the best of which for North America as a whole are probably Altig et al. (1998) for tadpoles and Altig and Ireland (1984) for larval salamanders.

Despite these non-inclusions, the *Key to the Herpetofauna of the Continental United States and Canada* is ultimately an eminently useful volume that I am glad to have available. The core purpose of any key is to identify organisms to their respective species, and for adult amphibians and reptiles of North America, no resource is better suited to the task than this book. While the authors have specifically pitched their product as an identification aid for university herpetology students, other audiences will find it equally useful. The careful prose, clear illustrations, and large glossary combine to make following the key easily comprehensible to interested amateurs with no formal background or training in herpetology, while the comprehensive coverage makes it by far the most convenient identification resource for herpetological professionals, especially those of us who are at a loss when confronted with a generic plethodontid.

Further, while the book is designed with preserved specimens in mind (even if the authors didn't say so directly in the introduction, the volume's dimensions—nearly identical to the copy of *Herpetological Review* in your hands—would be a giveaway), it is by no means deficient in allowing identification of live animals. This is especially the case when it is used in concert with the relevant Peterson Field Guide, where, thanks to the included cross-referencing, one can easily key out a specimen in hand and then turn to the relevant field guide entry for secondary confirmation. The *Key* is sturdily constructed and should stand up quite nicely to outdoor use, if such use is desired, while for indoor use the pages seem to be able to stand up to the occasional solvent drip. Overall, the *Key to the Herpetofauna of the Continental United States and Canada* is one of those rare volumes that all North American herpetologists and herpetophiles should own, and at a list price of around US $20 (or less online), there is little excuse for not picking up a copy.

A Checklist of North American Amphibians and Reptiles: The United States and Canada: Volume 1—Amphibians, Seventh Edition

M. J. Fouquette Jr. and Alain Dubois. 2014. Fouquette and Dubois, Tempe, Arizona and Paris, France. Softcover. 612 pp. US $34.99. ISBN 978-1-4931-7035-7.

MICHAEL J. LANNOO
Department of Anatomy and Cell Biology, Indiana University School of Medicine-TH, Terre Haute, Indiana 47802, USA
e-mail: mjlannoo@iupui.edu

In the America of the 21st century, a baffling 50% of the voting public claim to believe in special creation rather than evolution through natural selection. Therefore, it is curious that more people of the cloth, in their quest to reveal the inner workings of a supreme being, aren't roaming the bowels of our great museums examining specimens and working through nomenclatural history trying to figure out how to name these representatives of the five kingdoms and how they might relate to each other. Absent such divine intervention, it falls to mere mortals—the scientists—to work out the relationships of the tens of millions of species that constitute life on earth.

Fouquette and Dubois' book is the most recent attempt to document the species of amphibians in North America and their relationships to each other. I'll admit that the world of taxonomy and systematics is mostly foreign to me. As a rubber boot field biologist I simply want to insure that people know the species I'm working with, and where I'm working with them, so that should a new diagnostic technique reveal a different taxonomy, my successors can translate. In the one instance where I needed to know the current taxonomic and systematic relationships of North American amphibians (Lannoo 2005), I simply relied on the current authority (Crother 2000). My indifference (based on being very much aware of my shortcomings in understanding the rules of the International Code of Zoological Nomenclature and Hennigian systematics) does not mean that I underestimate the profound importance of taxonomy and systematics on the day-to-day professional lives of all the rest of us. I understand that everything we do rests on this foundation provided by our nomenclature. How can you run a business if you do not know your inventory? More specifically, how can we prevent the loss of a species if we disagree on how to define a species, and how can we prioritize taxa for conservation if we cannot agree on what to call them? My indifference simply means I've got no dog in this fight (although I wonder why Fouquette and Dubois chose to ignore our updated digital distribution maps, given Fouquette was a contributor to the effort). My plea to those who occupy the world of systematics is to provide stable names I can use, not choices that give the impression that I am taking sides in a war I would rather not be fought.

So, the first question is, where are the battle lines? Among the most important practical differences between Fouquette and Dubois and the Standard Names list compiled by Crother

(2012) are the retention (or resurrection, depending on your perspective) of the genus names *Bufo* for *Anaxyrus* and *Rana* for *Lithobates*. *Pseudotriton montanus* is placed in the genus *Gyrinophilus*. Fouquette and Dubois recognize *Batrachoseps aridus*, *Desmognathus aureatus*, *D. melanius*, *Eurycea wallacei*, and *Necturus louisianensis* as valid species. They recognize subspecies within *Bufo boreas*, *Rana clamitans*, and *Pseudacris streckeri*, but not within *Aneides flavipunctatus*, *Bufo debilis*, *Hyla avivoca*, *Rana sphenocephala*, and *Notophthalmus meridionalis*. They recognize as subspecies *Gyrinophilus porphyriticus palleucus* and *Siren intermedia texana*. Fouquette and Dubois also recognize the introduced species *Dendrobates auratus*, *Eleutherodactylus coqui*, *E. martinicensis*, *E. planirostris*, *Litoria caerulea*, *Leptodactylus fragilis*, and *Xenopus laevis*.

The second question then, is why do these battle lines exist? One answer resides in overall nomenclatural philosophy. Without attacking the Crother series directly, Fouquette provides a rationale for hostilities (p. 11):

> " … we firmly hold to the [International Code of Zoological Nomenclature] as the only authority for nomenclature of animals. Every so often some of us become dissatisfied with the *Code*, and introduce an alternative, which may have some advantages, but overall is unsatisfactory as a substitute. The current alternative system of nomenclature that enjoys a significant degree of popularity (which I assume is represented by Crother) is called the *Phylocode*. It purports to be based on the evolutionary history of animals, so that its rules are designed to name taxa that conform to evidence of their phylogenies, providing names for the major clades, in a looser system not requiring hierarchical ranking. We consider the Linnean system of a hierarchy of taxa to be one of the finest concepts that has been contributed to taxonomy. The system has been codified into a complex of rules for the proper naming of taxa, at least for species, genera, and family-series ranks."

Fouquette then goes on to dedicate his contribution to the memory of Stejneger, Barbour, and Schmidt (p. 13), "being the giants upon whose broad shoulders we may stand." Similarly, in their introduction, Crother's (2012) group addresses this same philosophy with a long quote from Stejneger and Barbour (1943) which can be summarized by the embedded sentence "But when the phylogenists begin to play with the nomenclature and want to express their (often very tenuous, sometimes fantastic) ideas in names, then goodbye to stability of nomenclature which we have been sweating for all these years …"

Another front in this war lies in the application of standard common names. Stejneger and Barbour (1943) used common names sparingly, while their successor, Schmidt (1953) used common names but without their emphasis. Three years later, Conant et al. (1956), in the second ASIH publication devoted to nomenclature presented common names as "standardized," in order to be "suitable for use by zoo and museum personnel, other writers of labels, guide books, and popular handbooks, camp counselors, biology teachers, professional zoologists whose chief interest is not herpetology, and anyone else who could make profitable use of such a standard list of names" (Crother 2012). Subsequently, Collins (1997) "strongly urged people to use such standardized common names." Fouquette and Dubois tie their intellectual lineage back to the time before the application of standardized common names with the sentence (p. 9), "The most recent edition of a herpetological checklist for North America (Schmidt 1953) appeared about 60 years ago." (This also explains the curious "seventh edition" designation of the title; Schmidt's 1953 treatise is the sixth edition.) In doing so, Fouquette and Dubois effectively ignore the work of Conant et al. (1956), Collins and his collaborators (first through fourth SSAR editions) and Crother and his collaborators (fifth through seventh SSAR editions; the fifth and sixth editions were also sanctioned by the Herpetologists' League and ASIH; in addition to these sponsors the seventh edition was sanctioned by the Canadian Association of Herpetologists, the Canadian Amphibian and Reptile Network, and Partners in Amphibian and Reptile Conservation [PARC]). Crother (2012) backs away from the term "common names," since such names differ by language.

A final front in this war rests in the use of paper vs. electronic formats for nomenclatural distribution. Fouquette and Dubois argue that a published paper checklist is critical as a nomenclatural document, which should be re-visited and republished on about half-decade intervals. That "when changes are made in an online checklist in 2001, then updated or modified in 2003, the original change may disappear and there is no record of the event." In contrast, Crother and his colleagues publish paper editions (for example, the sixth edition) with frequent online updates (v. 6.1, 6.2, etc.) leading up to a subsequent edition, published in paper (the seventh edition was published in 2012).

And so there lies the rub. As Dylan (1964) sang, "The line it is drawn. The curse it is cast." Where do we go from here, or perhaps the better question is, can we go anywhere from here? These are not trivial questions, because, as I point out above, names matter; and in some cases, where legislative wording leading to legal protection enters into the conversation, what you call something can mean life or death.

In taking a step back from the issues, it is obvious that Fouquette and Dubois face a daunting task in convincing herpetologists to take their side. All of the major in-print North American herpetological societies and a major conservation group (PARC) support Crother's list. And, while it would cost me $35 to purchase Fouquette and Dubois (with a re-purchase necessary every half-decade or so), I can download Crother as a PDF for free. Further, with Fouquette and Dubois being a self-published volume with its only institutional backing originating from Europe, it is unclear who will carry this battle forward, especially after the authors are unable. I sympathize with their struggle because I am a traditionalist (I prefer wool to polar fleece), but I'm also practical, (when I need to travel light I go synthetic). And I sure prefer "*Rana*" to "*Lithobates*" and "*Bufo*" to *Anaxyrus*," but I've gotten over it now and have learned to live with it.

In puzzling through this book, from its oblique introductory material carefully avoiding mentioning the society-sponsored checklists from 1956 to the present, to the "seventh edition" moniker, to the self-publication, I think I finally get it. Schmidt (1953)—the stated intellectual predecessor of Fouquette and Dubois—was published the very same year that Watson and Crick presented their discovery of DNA as the stuff of inheritance. And Fouquette and Dubois set their philosophical foundation squarely on the perspective of Stejneger and Barbour (1943; quoted above) lamenting the use of phylogenetic hypotheses in nomenclatural decisions, thus setting up the battle between the "Code" and the "Phlyocode." But the phylogenetic hypotheses of Stejneger and Barbour's day must have been clunky, or at least incomplete, by the standards of today, and certainly evolutionary hypotheses have been much improved by the application

of molecular tools developed since 1953. Indeed, these various forms of molecular techniques have been largely responsible for the huge increase in North American amphibian species now recognized by both Fouquette/Dubois and Crother/collaborators. It does seem ironic that Fouquette and Dubois recognize the use of molecular data in deciding species designations, but reject the branch-based pattern such molecular data derive.

I imagine way back in 1735, when he first published his newfangled "Systema Naturae," Linneaus had his detractors (especially among the botanists), and now the Phylocode is going through the same birthing pains. I'm reminded of another line, this one from the band Semisonic's (1988) song "Closing Time," borrowed from the Roman philosopher Seneca the Younger: "Every new beginning comes from some other beginning's end." Or, maybe not. Perhaps Fouquette and Dubois' argument has a shot; people of the cloth know an Old Testament story about David and Goliath.

Acknowledgments.—I thank Alan Resetar, Andrew Hoffman, Jaimie Klemish, Susan Lannoo, Rochelle Stiles, and Jonathan Swan for comments on earlier drafts of this manuscript.

Sanibel and Captiva islands lie in the Gulf of Mexico off Florida's southwest coast near Fort Myers. They are separated from Pine Island and the adjacent mainland by the brackish waters of Pine Island Sound and San Carlos Bay. Charles LeBuff and Chris Lechowicz have nearly seven decades of combined experience living and working on the islands, and their observations form the basis for this herpetofaunal natural history of the islands.

The book is very attractively produced, with a heavy-weight, glossy exterior covered with color photographs of six of the species of reptiles and amphibians found on Sanibel and Captiva islands. The binding is solid, and the book should hold together well.

Part I addresses Location, Geologic Formation, Climate, Land Use History, Hydrology and Water Management, Mosquito Control, Island Ecosystems, Species Recruitment, Environmental and Other Threats to the Island Herpetofauna, Early Herpetological Evidence, and Collection Techniques. This section is especially interesting and informative relative to the history of the islands, knowledge of which is critical to an understanding of their past and present herpetofauna.

Part II presents an Annotated List of the Amphibians and Reptiles of Sanibel and Captiva Islands, Florida. Sections within the species accounts include Other common names, Similar species, General range of the species, Island distribution, Preferred habitat type, Size, Color, Other characteristics, Diet, Reproduction, Call (for frogs), Life history, Population status, Threats, and Comments. Each species account is beautifully illustrated with color photographs by Bill Love, Daniel Parker, and others. Because some species have been seen only rarely on the islands, it is understandable that not all pictures are of Sanibel-Captiva specimens. Nonetheless, given the decades of work with *Caretta caretta* on the islands, I was surprised to see a photograph from South Carolina used to illustrate the hatchling of that species.

As the title suggests, this work is provincial and will be primarily of interest to residents and visitors to Sanibel and Captiva. This is especially so because no general map of the islands is provided. The somewhat anecdotal species accounts refer frequently to local roads and other features that will be known only to longtime residents. Periwinkle Way, Rabbit Road, and Las Conchas Road are intriguing names, but where are they? Perhaps of greatest interest to the non-islander will be 1) the history of the intentional introduction of *Lithobates grylio* or the invasion by *Pantherophis guttatus*, species native to the adjacent mainland

but apparently not to Sanibel-Captiva; 2) the chronicling of the extirpation or near extirpation of *Crotalus adamanteus*, *Drymarchon couperi*, and *Thamnophis sirtalis*; and 3) the surprising absence of *Agkistrodon piscivorus* and *Sistrurus miliarius* from the islands. The absence of *A. piscivorus* from the islands is especially enigmatic, as the species is known to occur on some much smaller offshore islands normally devoid of fresh water (e.g., Wharton 1969; Lazell 1989).

The authors acknowledge two fellow islanders for copyediting the manuscript and proofreading the final draft, and other than several cases of subject-verb disagreement, the text is relatively clean. However, the book would have benefited from the attentions of a good technical editor. It is easy for writers to read what they meant to write rather than what they actually wrote, and the book includes a number of factual errors, many of which the authors themselves would doubtless recognize. Errors are relatively few in those sections dealing with Sanibel-Captiva, but they magnify when the discussion wanders from the islands.

Particular problems arise when the discussion of general ranges becomes confused, leading to gross overstatement of ranges. For example, we read that "The southern ring-necked snake is found throughout the eastern U.S. and southeastern Canada from the Florida Keys to Nova Scotia, and as far west as…Minnesota in the north and Arizona in the south." Similarly, we read that "The southern black racer is found throughout the southeastern U.S. [with]…isolated populations in west Texas and a subspecies that ranges into Mexico from South Texas." In both cases the range of the stated subspecies has been expanded to include the much broader range of the species.

The composite account for *Trachemys scripta* indicates that *T. s. scripta* "ranges from northern Florida to southeastern Virginia." Oddly, the following sentence reads, "It is not native to Florida but is now found throughout the state as a result of escaped or released pets." The latter sentence would have been true of *T. s. elegans*, but *T. s. scripta* is native to the entire Panhandle region of Florida. Also within the *T. scripta* account, we read that females of the species range from 19 to 30 cm in carapace length, with maxima of 28 cm for *T. s. scripta* and 28.9 cm for *T. s. elegans*.

The native range of *Python bivittatus* is said to span the Indian subcontinent, a region instead occupied predominantly by *P. molurus*. The following sentence then correctly outlines the range of *P. bivittatus* as extending from eastern India through Southeast Asia to southern China and into Indonesia.

The venter of *Coluber constrictor priapus* is said to be white, whereas it is actually black, as can be seen in the accompanying photograph. *Caiman* "*crocodilis*" is thrice misspelled. *Hyla squirella* is said to be "found throughout…Florida, excluding some barrier islands and the Keys," whereas it is actually found throughout the Florida Keys (Lazell 1989; Krysko et al. 2011). *Kinosternon baurii* is said to be "…found mostly in the coastal plain of Georgia, the Carolinas, and Virginia", which is presumably not what was intended, as the species occurs commonly throughout peninsular Florida. *Pseudemys peninsularis* is called both peninsula cooter and peninsular cooter. "Picking individual [box] turtles up as pets" is erroneously said to now be prohibited, whereas individuals in Florida may pick up one box turtle per day, with a possession limit of two (Florida Administrative Code 68A-25.002[6]).

Crocodiles often bask with the mouth agape. The book presents the oft repeated but poorly documented explanation that this is a method of thermoregulation. Downs et al. (2008) briefly discussed some of the shortcomings of such an explanation. Is gaping behavior to facilitate heating or cooling? The crocodilian mouth is neither moist nor highly vascularized. Gaping behavior can occur in the early morning and at night. I recall early one cold morning in South Africa walking past a birdbath glazed with ice and then seeing Nile crocodiles basking with mouths agape. Loveridge and Blake (1987, p. 260) provided a photograph of a large *Crocodylus niloticus* immobilized with gallamine; the fully relaxed animal sits with mouth agape, just as seen in basking individuals. The intuitive explanation of thermoregulation seems inadequate.

The glossary that follows the species accounts includes some terms for which definition seems unnecessary (e.g., diminutive, diurnal, erosion, habitat, insular, National Wildlife Refuge System, pathogen). The neologism "deteologic agent" appears in both text and glossary where "etiologic agent" is intended. Watershed is given a definition more apt for drainage divide. And botanists will be surprised to learn that taxonomy is "The science of naming animals".

The book ends with lists of Suggested Reading and Literature Cited. Conant and Collins (1998) is included in the suggested reading, but it is not included in the Literature Cited, despite the fact that the sizes reported in most species accounts were obviously taken directly from that classic work.

In summary, this book is very attractively produced, and it is destined to long grace many a coffee table on Sanibel and Captiva. Visitors to the islands and residents will find the sections on geology, hydrology, and land use history informative. Otherwise, though, the book will not be of particular interest to most readers.

STEPHEN D. BUSACK
North Carolina Museum of Natural Sciences, Raleigh, North Carolina 27601, USA; e-mail: sbusack348@aol.com

Spain has continental Europe's highest reptile diversity; 71 naturally-occurring species inhabit its borders or visit its shorelines. In comparing the former version of this guide (*Reptiles Españoles*; Salvador and Pleguezuelos, 2002; see Busack 2003) to the current volume, one immediately notices several taxonomic changes. Increased understanding of phylogenetic relationships among Iberian taxa (due primarily to extensive DNA research) has resulted in reassignment of four snake species to different genera: *Coluber hippocrepis* to *Hemorrhois* Boie, 1826, *Coluber viridiflavus* to *Hierophis* Fitzinger *in* Bonaparte, 1834, *Elaphe longissima* to *Zamenis* Wagler, 1830a, and *Elaphe scalaris* to *Rhinechis* Michahelles *in* Wagler, 1830b. In addition, three subgenera formerly considered closely related within *Lacerta,* and now understood to represent evolutionary lineages distinct from *Lacerta sensu stricto,* warrant re-assignment as well. For *Lacerta lepida* its former subgenus, *Timon* Tschudi, 1836, is appropriate, and the species is now correctly known as *Timon lepidus*. Similarly, *Lacerta* is replaced by *Scelarcis* Fitzinger, 1843, for *S. perspicillata,* and by *Zootoca* Wagler, 1830a, for *Z. vivipara*. *Lacerta monticola* and *L. bonnali* are also no longer considered representative of *Lacerta* and are assigned to the recently defined *Iberolacerta* Arribas, 1997 (see also Arribas 1999). Former subspecies elevated to species include *Iberolacerta cyreni* (Arribas, 1996) (formerly within *L. monticola*); *Iberolacerta martinezricai* (Arribas, 1996) (formerly within *L. cyreni,* see Arribas and Carranza 2004); *Iberolacerta aranica* (Arribas, 1993) (formerly within *L. bonnali*); *Podarcis carbonelli* Pérez Mellado, 1981 (formerly within *P. bocagei,* see Sá-Sousa and Harris 2002); *Podarcis vaucheri* Boulenger, 1905 (formerly within *P. hispanica*); *Psammodromus edwardsianus* (Dugès, 1829) (formerly within *P. hispanicus*); and *Chalcides coeruleopunctatus* Salvador, 1975 (formerly within *C. viridanus*). *Blanus mariae* Albert and Fernández, 2009; *Iberolacerta galani* Arribas, Carranza, and Odierna, 2006; *Iberolacerta aurelioi* (Arribas, 1994); and *Psammodromus occidentalis* Fitze, Gonzalez-Jimena, San-Jose, San Mauro and Zardoya, 2012, are recently described additions to the fauna. *Macroprotodon brevis* is now the correct appellation for mainland Iberia's population, and *M. cucullatus* is correctly applied to populations found in the Balearic Islands (Crochet and Dubois 2004). The Canary Island Giant Lizard on Gomera Island (*Gallotia gomerama* in Salvador and Pleguezuelos 2002) is currently assigned to *G. bravoana* Hutterer, 1985 in this *Guía* (see Bischoff 1998, for details).

Teira dugesii from the Archipelago de Madeira, and Portuguese distributions for all species found both in Spain and Portugal are no longer included. Persons interested in distributions for Portugal may consult Loureiro et al. (2008) for coverage. *Saurodactylus mauritanicus* is no longer found on Isla de Alborán and has also been omitted from the current version.

This volume is essentially a 2013 update of the now out-of-print *Reptiles Españoles* and, as with that edition, it is more an informational treatise than the typical field guide. The authors, each a well-positioned professional (Salvador at the Museo Nacional de Ciencias Naturales, Madrid, and Pleguezuelos [currently president of the Asociación Herpetológica Española (AHE) – Spain's answer to SSAR] at the Universidad de Granada, have up-dated natural history information, included both replacement, and additional, photographs, and completely revised distributional information using the AHE's computerized data base of nearly 200,000 records. Each species account is introduced by a generally superb color portrait that often includes an insert illustrating the head. Species identification is facilitated by Salvador's excellent line drawings, both in diagnostic keys and within species accounts. The bibliography guiding the user to additional information found at the conclusion of each species account in the former edition is, however, no longer provided in this edition and readers are encouraged to visit www.vertebradosibericos.org for continually updated information. Errors noted in the former edition have been corrected, but two photographs are labeled incorrectly: the juvenile turtle pictured on p. 44 is *Emys orbicularis,* not *Mauremys leprosa,* and the female *Podarcis carbonelli* pictured on page 245 is actually a male.

The degree of reptile species diversity present in Spain places an elevated responsibility upon the country for facilitating conservation. While both editions address general threats to survival and protective legislative measures among comprehensive introductory materials, species accounts in this version also contain a "State of Conservation" section. Survival status within Spain, as well as status throughout a species' entire range, are each provided and specific threats are elaborated in this section. The stated degree of concern for *Gallotia galloti* (p. 350) is incorrect, it is actually considered to be of "minor concern." Survival of *Iberolacerta aurelioi,* an endangered species restricted to the Pyrenees Mountains, is threatened by ever-increasing vehicular traffic and alteration or destruction of habitat due to the construction and maintenance of infrastructure required to support skiing, trekking, and hydroelectric power generation. Only ten years on the faunal list and already this unique species is being threatened by man's activities in rugged mountainous areas of northern Spain, southern France, and northeastern Andorra.

Introduced species are becoming a disturbing feature of life among the earth's expanding and increasingly mobile human population, and the former edition reported introductions of *Anolis carolinensis, Pelodiscus sinensis, Pseudemys picta,* and *Trachemys scripta*. As serious threats to aquatic systems, all turtle species, in my opinion, should be considered invasive species when introduced to non-native habitats, and be closely monitored and/or controlled where necessary. The 2013 edition reports significant expansion between 2002 and 2013 in localities reporting *Trachemys scripta* (see maps, p. 46, in each edition). This turtle, once ubiquitous in the United States wherever pets are sold, is now more widely-distributed in the autonomous regions Catalonia (especially around Barcelona) and Andalucía

(especially around Sevilla, and coastal portions of Málaga, Granada, Cádiz, and Huelva Provinces) than reported in 2002. In this edition the New World endemic is newly reported from autonomous regions Castilla-La Mancha and Galicia (Pontevedra Province), and appears widely-distributed throughout Madrid Province. A newly added section, "Introduced Snakes in the Canary Islands," informs us that the parthenogenetic *Ramphotyphlops braminus*, discovered on Gran Canary Island in 2004, and *Lampropeltis getula*, discovered there in 1998, can today be considered established introductions. The kingsnake eradication campaign that began on Gran Canary Island in 2007 did locate and remove 92 specimens from the wild in 2008, and an additional 131 specimens in 2009—an indication there is an established population on Gran Canary Island.

Producing a guide to the fauna of any area is extremely complex, and these authors have done an admirable job capturing and incorporating recent data in light of the massive increase in herpetological research being done in Spain today. While new maps suggest a slightly reduced number of records for some species, these maps are more accurate than those previously presented because AHE's database includes only checked and verified distribution data. When I noted some quadrants on sea turtle maps non-randomly colored a darker blue than others, I queried the authors. The darker blue quadrants are those from which fishing boats, etc., had reported at-sea sightings and the small red circles along the shoreline represent records from beaches and harbors. This explanation was inadvertently omitted from the Introduction.

Psammodromus hispanicus is listed in the tables of contents, alphabetical indexes and species keys for each volume as a single entity. In 2002 this species was considered to be represented by two subspecies, but recent investigations by Fitze et al. (2011, 2012) have determined *Psammodromus hispanicus*, *Psammodromus edwardsianus*, and *Psammodromus occidentalis* to be separate lineages and this version incorporates this recent taxonomic rearrangement in a single section (pp. 289–294). The frontispiece, unlike the four color plates in the species account, however, is not labeled as to species but is suggestive of *Psammodromus occidentalis*. Line drawings in this section have been reprinted from the earlier edition and likely represent *Psammodromus hispanicus*, but are not so-labeled. Fitze et al. (2012: Fig. 1) provide a map of "prospective" distribution for the three species but this edition includes only one map for all three species without any suggestion as to which species may be found where. The variation section does present a broad delimitation of ranges as understood for these recently distinguished taxa, however. Explanation for these anomalies of presentation in an otherwise up-to-date, well-presented guide are likely the result of two competing issues: independent genetic lineages (species) identified using DNA techniques are often difficult to distinguish morphologically (see color photographs in the present edition) and placement in the species key may not have been appropriate at the time this volume went to press (all species could have been listed together in the key couplet leading to *Psammodromus hispanicus*, however). The map for the two species of *Blanus* (p. 91) also lacks indications regarding prospective distributions. In any event, users of this guide are informed with regard to these newly discovered taxa and made aware of problems involved with casual identification and determination of precise distribution limits.

In the realm of popular guidebooks, this *Guía* is, as was the earlier edition, lavishly illustrated and very well-presented. If you are already interested in European reptiles you will find it a necessary addition to your bookshelf. If you have not yet visited Spain, or enjoyed this country and experienced the excitement of your first encounter with its reptile fauna, now is the time—and this is the one guide you will find most helpful.

Since publication of the Hillis et al. (1996) classic review *Molecular Systematics*, technological advances in the rate and amount at which various classes of molecular data can be collected, coupled with cost reductions and increased computational power for analyses of large data sets, have fostered a steady expansion of the kinds of biological questions to which molecular data sets are being applied. The dizzying pace at which these advances have occurred challenges investigators to keep abreast, and this review by Gamble provides a thorough but easily accessible review of methods for collecting and preserving genetic material for a broad range of research themes in herpetology.

The publication includes a brief Introduction in which Gamble emphasizes that studies of amphibians and reptiles have been at the leading edge of many of these advances, and given the time and cost of field work, the collection and preservation of samples for molecular studies is the single most important component of these research programs. The text is for people with a basic background in biology, and complements the work of Simmons (2002) on how to collect, euthanize, and preserve voucher specimens for museum collections, and Beaupre et al. (2004) for guidelines to practical and ethical issues in herpetological field and lab research.

The first two of the paper's four chapters are short. Chapter 1, "Why collect genetic material?," summarizes the many uses of molecular data in biological research, what tissues are collected and how they are preserved, whether these will be acquired via loans or field collected, and whether field work is general (as in poorly-sampled regions), or targets specific taxa. Gamble identifies three emerging trends that are likely to increase exponentially: genomics (see Haussler et al. 2009, for details), studies of amphibian pathogens, and species identification via DNA barcoding. Each of these topics is further elaborated in separate paragraphs, and the final point made is that properly archived tissues can also be used to detect environmental contaminants or in stable isotope studies of foodwebs. Embedded Box 1 describes methods for extracting/sequencing DNA and detection of the *Batrachochytrium dendrobatidis* (*Bd*) fungus, as well as targeted enrichment and next-generation technologies for sequencing fragmented DNA from formalin-fixed/ethanol-preserved museum specimens, but emphasizes that most of us will continue to need access to field-collected tissue samples archived for molecular genetic studies. Chapter 2, "The Science of Preserving Genetic Material," describes processes by which DNA and RNA may be degraded if improperly preserved and stored under field conditions, and ways to protect field-collected samples.

Chapter 3 is the longest and devotes 18 pages to "Methods for Collecting and Preserving Genetic Material," and includes eight figures and three boxes. The introductory paragraphs and Box 2 summarize "Things to avoid when storing genetic material." The topical coverage is extensive and begins with a "Permits and Ethics" section that emphasizes laws governing collection and transportation of wildlife, and those related to animal safety and welfare. This is followed by a short "Euthanasia" section summarizing means of humanely killing amphibians and reptiles that are usually acceptable to institutional Ethics Committees for this type of research.

The next three sections, "Documenting Samples," "Sample Containers/Packaging," and "Sampling Tissues from Specimens," offer clear descriptions and illustrations of accepted means of properly documenting collection of specimens. These include taking detailed field notes, geo-referencing localities, and field tagging specimens and tubes in which tissues are stored. Several methods are described for numbering tubes and also for maintaining field-collected samples so as to minimize degradation of nucleic acids. The last section covers types and amounts of tissue to be sampled, storage to minimize degradation, collection of "back-up" samples on filter paper blots, and treatment of scissors, forceps, etc. between excision of tissues to minimize cross-contamination. A separate paragraph is devoted to treatment of samples from which RNA will be extracted.

The "Nonlethal Sampling" section is one of the most extensive, and is justified by the many studies in which individuals must be non-lethally sampled (species of conservation concern, re-sampling of individuals through time, permitting issues in protected areas, etc.). Methods are described for collecting five classes of samples: buccal/cloacal swabs, blood, biopsies/tail/toe clips, shed skins, and "other," which includes DNA from mosquito blood meals (think "Jurassic Park"), frog DNA from carrion flies, dried snake venom, bone fragments taken from notching turtle shells, and reptile eggshells.

A short paragraph describes "Sampling Pathogen DNA," which may include: blood to detect lizard malarial parasites, skin swabs for amphibian *Bd* (which is illustrated in Fig. 7 and presented in detail in Box 3), liver or kidney (preferred) and toe or nail clips (less sensitive) to detect Ranavirus.

The final section in this chapter describes "Cell Culture," which is likely to be the least familiar protocol to most herpetologists; this requires collection of some tissue type under sterile conditions, which is then stored in a cell culture medium for establishing fibroblast cell cultures in a lab incubator. In my own experience, field-collected animals can be euthanized in a lab and tissue excision performed under sterile conditions in a laminar-flow hood. Sterile cells are then minced in a growth medium to establish fibroblast cultures for harvest; cultures may be subdivided to establish new cultures to increase cell populations available for harvest. In my example cultures were treated with colchicine to harvest metaphase chromosomes for cytogenetic studies (Sites et al. 1979), and we successfully extended the protocol to field conditions (sampling/storing mammalian ear clips under sterile conditions in a portable plexiglass field hood; Sites et al. 1981). Ideally, tissues are frozen slowly for LN^2 transport, although before the days of Mr. Frosty, this was not possible or necessary (Sites et al. 1981).

The final chapter, "Storage, Curation and Transportation of Genetic Material," provides thorough coverage of storing tissues, emphasizing the value of fresh tissues above all other kinds of samples for most studies, but also that there is no single preservation method for every possible downstream use. A short "Cryopreservation" section emphasizes flash freezing of tissues in LN^2 as most effective for preserving the highest quality DNA and RNA, and how this can be done. This is followed by short section on "Desiccation," and then an expanded treatment on "Fluid Preservation," which is most relevant to researchers working in remote areas without access to any form of cold storage. Under these conditions high-salt solutions (RNAlater®) or 95–100% ethanol are the preferred media for keeping DNA/RNA intact, but because ethanol is considered a hazardous material (flammable), shipping ethanol-stored tissues requires proper documentation and package labeling. A final section described other fluid preservatives, followed by a short paragraph on "Long-term Tissue Storage." A brief but important section covers "Shipping" of tissue samples, and the last describes "Museum collections"; both of these are rich in detail and will inform researchers from multiple disciplines. Gamble emphasizes archival of tissues in research collections that link to online databases (HerpNet, VertNet, etc.), and eventually standardizing links between published sequences, tissues, and voucher specimens. When voucher specimens are not available (non-lethal sampling), options include use of DNA barcodes to verify identifies. Lastly, because tissue collections are unique in that loans usually not returned after use, amplification of whole genomes (using GenomiPhi) would permit return of the loan as an amplified genomic sample.

I found this contribution to be clearly written, well-organized into a logical sequence, with figures and boxes appropriately placed in the text, and no missed citations. Figure 4 would convey more clarity if it had been a more close-in photo, but overall Gamble has contributed a publication that will be of great service to multiple groups of researches both in and far beyond the taxonomic boundaries of herpetology.

Mountain Dragons—In Search of Chameleons in the Highlands of Kenya

Jan Stipala. 2014. Privately published (available from the author, at 2 Murtons Terrace, Lanner, Cornwall, TR16 6HW, United Kingdom). 124 pp. Hardcover. £26.00 (approximately US $42.00). ISBN 978-0-9928176-0-2.

STEPHEN SPAWLS
7 Crostwick Lane, Spixworth, Norwich NR10 3PE, England
e-mail: stevespawls@hotmail.com

The late Alex Duff-MacKay, senior herpetologist at Kenya's National Museum for 30 years, once wrote that chameleons "can melt the heart of bank managers" (MacKay 1994). Beautiful, brightly-colored charismatic lizards of Africa and its surroundings, chameleons have found their niche in the highlands of eastern and south-eastern Africa. Tanzania has 40 species and Kenya has 24, many endemic. No other mainland African country approaches those sorts of numbers. Those that entered the forests have developed strange, often unfathomable head ornamentation. Chameleons have inspired many enthusiasts, generated Facebook groups and stimulated the production of richly-illustrated books, for example Necas (2004), Tolley and Burger (2007), and Tilbury (2010). The book by Tilbury, a medical doctor and lifelong chameleon enthusiast who travelled the length and breadth of Africa in search of

chameleons, was regarded as the last word. But since its publication several new species have been described. Now biologist Jan Stipala has made his contribution, with this beautifully produced, large format book (30 × 30 cm, an unusual size).

This book is proof of what you can do with a bit of enthusiasm. Stipala spent a year exploring the magical mountain forests of the highlands of Kenya, in a battered Toyota Land Cruiser that he bought cheaply, accompanied by herpetologists from the National Museum of Kenya and game scouts. When the team managed to get the vehicle back from the repair shop and into the field they got stuck in the mud, frozen and soaked at high altitude, had encounters—some scary—with elephant and buffalo, were stalked by a leopard, and had a drunken game scout shoot a hole through the roof of the Land Cruiser. But, in the high country they also located, and described two new species of chameleon (Stipala et al. 2011, 2012), one of which required a wet four-day trek onto Mt Kinangop in the southern Aberdare Range. They also recorded a Tanzanian and a Sudanese species in Kenya for the first time, and documented numerous range extensions. These are all documented here.

The book opens with several full-page and double page photographic spreads of chameleons and their habitats. There follows a preface, introduction and rationale, some useful maps and background information on the landscape, climate, geological history of highland Kenya and fieldwork techniques (including a page on how to catch chameleons). There is a seventy-odd-page travelogue, describing the team's adventures visiting 12 mountain massifs of southern and western Kenya, two pages on chameleon farming, twelve pages of species profiles documenting eleven Kenyan chameleon species, nine pages detailing the research, a page on chameleon photography, an index and a short bibliography of 23 pertinent references. The species profiles have three or four representative pictures, a map with spot localities, an elevation profile and entries under the headings: size, description, distribution, ecology, behaviour, reproduction and taxonomic comments. The maps greatly expand our knowledge of the range of these species within Kenya, every species shows range extensions beyond that documented by Spawls et al. (2002). The research section has some useful phylogenetic trees and maps showing haplotype distributions. I noted with interest that these interlace elegantly with the known dates of uplift of the various sections of the Kenyan Rift Valley and the associated volcanic mountains (Spawls and Mathews 2013).

The text is lucid, entertaining, and informative; Stipala's easy style reads well. The color photos are one of this book's strengths. There are over 360, showing the land and the chameleons. The habitat pictures are superb, with panoramic views that would not be out of place in *National Geographic*. The chameleon pictures are equally good, illustrating some 12 species of Kenyan chameleon, some the first records for the country. Many are finely composed, showing the animal relaxed in the landscape, and all are taken by daylight; a refreshing technique in these days when the general consensus seems to be that chameleons are best photographed by flash, at night, after infuriating them into displaying defensive colors, and then boosting the colors digitally. There is an astonishing sequence of pictures, showing two vivid blue-green and yellow Jackson's chameleons (*Trioceros jacksonii*) from Machakos having a scrap in a coffee bush. It's all here, the attendant female, the confrontation, the horns locking, finally the defeated male changes color and slinks off. And sadly the female then rejects the victor, hissing at him to keep away. The course of true love hardly ever runs smooth!

Stipala concentrated his research on two species, *Trioceros jacksonii* and *T. hoehnelii*, and the morphology section is largely concerned with these two species, with data on body size variation, how it correlates with elevation and a Principal Component Analysis of head morphometrics in *T. hoehnelii*. The bulk of the photographs are of these two species. I thought I knew both but there are color varieties and forms here that I have never seen, from places where I would not have thought of looking. I know the dry coniferous forest of the northern slopes of Mt Kenya fairly well, but have never found a chameleon there. I gnashed my teeth to find out that there is a Jackson's Chameleon there with bright blue and orange skin around the eye!

At £26 or US $42, this book represents remarkable value for money when you consider how much many specialized reptile books cost nowadays. I perceive a few shortcomings; there are 75 pictures of *Trioceros jacksonii* and 63 pictures of *T. hoehnelii*, an indulgence that can creep in when you are your own editor. By cutting some of these Stipala could have covered a few more of Kenya's chameleon species. I would liked to have seen details of the localities shown on the spot maps. There is the odd typo; Stipala has managed to lose one of his own co-authors from the citation of their description of *Trioceros kinangopensis* (Stipala et al. 2012). But overall, this is a bewitching, beautiful book, it brings alive the landscape, the chameleons, and the ordinary citizens of highland Kenya. All chameleon enthusiasts, East African herpetologists, and Kenyaphiles will want it—and many will want to visit. Jan Stipala has taken us into the heart of highland Kenya and its enchanting chameleons.

Tracks and Shadows. Field Biology as Art

Harry W. Greene. 2013. University of California Press, Berkeley & Los Angeles, California (www.ucpress.edu). xiii + 280 pp. Hardcover. US $29.95. ISBN 978-0-520-23275-4.

BILL BRANCH
Bayworld (Port Elizabeth Museum),
P.O. Box 13147, Humewood 6013, South Africa
e-mail: williamroybranch@gmail.com

For those who don't know, Harry Greene is the Stephen H. Weiss Presidential Fellow and Professor of Ecology and Evolutionary Biology at Cornell University, a recipient of the E.O. Wilson Award from the American Society of Naturalists, and a recently elected member of the American Academy of Arts and Sciences. Previously he spent 20 years on the faculty of the University of California at Berkeley, where he played a seminal role in interpreting the phylogenetic context of reptile behavioral ecology (Greene 1973, 1979, 1983, 1986, 1988, 1994a, 1999). The quality of Greene's writing is superb, as demonstrated by his previous book (1997) — *Snakes: The Evolution of Mystery in Nature* (hereafter referred to as *Snakes*) — which won a PEN Literary Award.

Unless you know Harry Greene or what he does, however, there is not much in the title of this book to signal its herpetological interest. The cover shot of Peringuey's Adder (*Bitis peringueyi*) side-winding across Namibian dunes may give some indication into the scope of the inner essays, but not the blub on the dust wrapper: "Intellectually rich, intensely personal, and beautifully written, *Tracks and Shadows* is both an absorbing autobiography of a celebrated field biologist and a celebration of beauty in nature." This is an accurate and nice summary, but the book could still be about flowers or pretty bovines.

Tracks and Shadows is divided into three parts. The first, 'Descent with Modification,' is a nice play on the forces that influence the trajectory of an individual life. It elegantly interweaves the punctuated equilibria that result from the impact of tragedy and renewal. Whilst in essence this is part autobiography, the story also entwines the lives of other herpetologists, particularly Henry Fitch who mentored Greene in his early studies. Fitch's early, quiet, formative influence is in contrast to Greene's own wild, disrupted youth. Many will be surprised at some of the events relived in these pages. It certainly made me realize how simple and peaceful has been my own journey. Meaning in life is not an objective but a personal perspective, and this section of *Tracks and Shadows* reiterates the impacts of pain and renewal that characterize a life's journey.

In the middle section, 'Conversing with Serpents,' Greene retraces his own broad studies on different groups, particularly the various aspects of what it means to be a snake. It covers the period in which Greene's studies and papers really influenced conceptual thinking in herpetology and in the evolution of behavioral ecology. Henry Fitch had patiently documented the autecology of Kansas reptiles, many of which were summarized in his monograph on *A Kansas Snake Community* (Fitch 1999), and various reviews of reptile biology (1981, 1982). The youthful Greene was more synthetic in his approach, placing these and other observation in a more phylogenetic context. This section, however, is more than historical narrative as it also introduces a more general discourse on what it means to be a field biologist.

On starting this review I glanced at *Snakes*. It is full of good prose and insight. This time I happened to open at the chapter on basal snakes, and noted a sentence on increasing insight into the lives of Boa Constrictors. The section reads: "Some tantalizing chance observations suggest that the best is yet to come, that there is much more to being a huge serpent than we realize." The quote captures both Greene's fresh style and questioning mind, but I bet even he was later gob-smacked when learning that boas (Booth et al. 2011a) and other species (Booth et al. 2011b, 2012) may undergo "virgin births" (facultative parthenogenesis), displaying previously unappreciated reproductive flexibility. Moreover, Indian Pythons are now known to display "homing" abilities (Pittman et al. 2014), admittedly a poignant and problematic term for discoveries made on an introduced Florida population. These are sophisticated behaviors, and highlight how easily our anthropocentric ego confuses "basal" with "primitive." Greene may be right when he notes that "A book that captures the majesty of giant snakes has yet to be written," but his own brief summary (Chapter 9) makes a good start.

In the final section Greene allows himself to ponder larger issues and present his views on the central role of organismal biology and the enlightenment that comes from contemplating nature. Science and the humanities are often juxtaposed as if they were alternate views of Life, as if a scientific outlook somehow deprived the world of beauty and poetry. The distinction between these two cultures (Snow 1959) is artificial, and belies the creativity that attends scientific insight. By fieldwork Greene doesn't mean prosaic mud and fresh air, but rather the opportunity to observe and discover. It is not simply observed natural history, although both Fitch and Greene have defended the value of the anecdote. Rather, it is seeing Life's inter-relatedness, opening oneself to the opportunity for the creative moment when the forest becomes more than the trees. Greene's prose and evocative text ("mud-smudged") says it much better.

It is difficult to find suitable language to describe new discoveries of the rich, subtle complexity of reptile life. In part, Science has been its own enemy, insisting on non-emotive descriptions. Yet, the natural fear associated with snakes because of a venomous minority requires vigorous rebuttal and positive appeals. Too often public perception views evolution as laddered, with "lower vertebrates" primitive, governed by instinct and possessing limited behavioral flexibility. Greene argues against anthropomorphizing animals, but has been challenged (Walker, 2014) for this same "sin" when he notes "that blacktail and timber rattlesnakes hunt mammals, lie around after big meals, search for mates and wrestle with rivals, court and mate, give birth, and attend their young." However, none of these actions (hunt, lie, search, wrestle, court, mate, attend) are anthropomorphic. They are simple verbs that describe the parameters of Life. That they should be considered only applicable to humans, and their use in describing snake behaviors as anthropomorphic, perfectly reflects the modern lack of "connectedness" to wildlife that is one of Greene's major concerns.

Concern for the loss of Natural History as a central axiom of biological science is a common theme in Greene's publications (1993, 1994b), and is increasingly noted in other works (Tewksbury et al. 2014; Wilson 2014). For some, I am sure, it thus seems paradoxical that Greene centers himself within the natural world via hunting, by insisting that he embrace the predator within. Personally I do not find this necessary but as I live in Africa,

perhaps I'm more aware of the coin's flip side. Greene is also an advocate of Pleistocene re-wilding to repair and reintegrate damaged ecosystems. In the North American context it urges the re-introduction of large mammals and their associated predators, or ecological proxies where these have become extinct. This is already happening, albeit in a limited, non-threatening, and easily reversible manner, using giant tortoises as surrogate herbivores (Burney et al. 2012, 2013; Griffiths et al. 2013). These selective grazers are being used to clear island ecosystems of alien vegetation after the extinction of indigenous avian grazers (e.g., the Dodo in the Mascarenes and the *moa nalo*, a flightless duck, in Hawai'i). However, re-introduced large mammalian herbivores and carnivores may come into more direct conflict with humans. In Africa I have stumbled into lion and buffalo whilst herping in the bush, and have also come too close to crocs and hippo when preoccupied with collecting frogs at night. These are real dangers, and although Greene notes that deaths from lion in Tanzania did not make the top 50 mortality categories in the country, this is no solace to the 40 families bereaved by lion kills each year.

This book is subtitled "Field biology as art," and Greene states that "I aim to persuade others to get out there and learn more about themselves." The biggest challenge for many may be finding their place in an indifferent universe, and regaining a lost connectedness to our biological heritage offers a rebuttal to a human arrogance that demands dominion over the whole Earth. In the preface to this beautiful book, Harry writes of the acceptance of personal loss: "Studying predators, I contemplated violence without evil, death without tragedy." Later he delights in finding a lost and favored quote — *The Earth is mostly a bone yard, but pretty in sunlight* (McMurty 1985). This review ends with my own favorite aphorism, anonymous and black, and taken from my son's surfing magazine a generation ago. I offer it in thanks for a book that is timely, thought-provoking and which, more simply, I thoroughly enjoyed.

"It's not that Life is short it's just that you're dead for such a long time."

The New Mexico Ridge-nosed Rattlesnake
Tell Hicks — oil on canvas 26" x 20"

The Ridge-nosed Rattlesnake (*Crotalus willardi*) is one of the smallest rattlesnakes found in the USA and northwestern Mexico. It is a montane species with a very limited distribution. The New Mexico Ridge-nosed Rattlesnake (*C. w. obscurus*), one of five subspecies currently recognized, occurs in the Sierra San Luis in Sonora, Mexico, as well as the Animas and Peloncillo Mountains of New Mexico. Its total range includes the Sierra San Luis, in Mexico, and the Animas Mountains and Peloncillo Mountains of New Mexico and extreme southeastern Arizona. It is listed as a Threatened Species under the U.S. Endangered Species Act and is fully protected.

This painting, by wildlife artist **Tell Hicks**, depicts the snake in typical habitat in the remote Peloncillo Mountains. It will be used as the cover artwork for a forthcoming book, *The Rattlesnakes of Arizona*, edited by Gordon Schuett, Randall Reiserer, and Charles Smith. The book will included peer-reviewed contributions from leading rattlesnake researchers, and will feature over 20 highly detailed illustrations by Hicks. The book's release is set for late 2014 (ECO Publishing; ecouniverse.com).

Tell Hicks is a professional wildlife artist, specializing in reptiles and amphibians. He was born in London and has a studio in Somerset, in the UK, where he lives with his wife and family. A founding member of the International Herpetological Society in the 1960s, he has recently served as its President. He is an active conservationist and in the 1960s assisted with the field study that successfully led to the legal protection of Britain's most endangered amphibians and reptiles.

As a teenager, he worked in British zoos before travelling through Europe and Asia, to Australia, catching and painting reptiles and other wildlife along the way.

His passion for herpetology and natural history continues to take him around the world, gathering material for his highly detailed paintings, and he regularly gives talks to wildlife groups and natural history societies, about his work and travels to such places as Turkey, Cyprus, Canary Islands, Australia, New Zealand, The Galapagos Islands, Peru, and the USA.

Tell has won major awards within the screen-printing industry, for his t-shirt designs, and still produces work for Eco and other leading t-shirt printers in the USA and Europe. Examples of his paintings are on display in several museums, including the Chiricahua Desert Museum, Rodeo, New Mexico, where his large mosaic of a Gila Monster and 16-ft metal sculpture of a rattlesnake tail can also be seen.

Many of his paintings are available as limited edition prints from www.tellhicks.com (Europe), or www.ecouniverse.com (USA) where t-shirts and caps featuring his artwork are also available.

ABOUT OUR COVER: *Eurycea cirrigera*

Salamanders of the genus *Eurycea* are a diverse and widespread group in the eastern and central United States. They vary significantly in natural and life history, including several groups which exhibit paedomorphosis. Bonnett et al. (2014. Evolution 68[2]:466–482) examined the evolutionary history of metamorphosis in spelerpine salamanders and demonstrated a positive correlation between the evolution of paedomorphosis and both cave-dwelling and arid surface environments. In *Eurycea*, several lineages have independently evolved paedomorphosis, including a clade of subterranean species from the Edwards Plateau of Texas, multiple populations of *E. tynerensis* in the Ozark Plateau, the aquifer-dwelling *E. wallacei* of the Southeast, and the recently described *E. subfluvicola* of the Ouachita Mountains (Bonnet et al. 2014, *op. cit.*; Steffen et al. 2014. Zootaxa 3786[4]:423–442). The Two-lined Salamanders (*E. bislineata* complex) are a widespread clade with five described species. Generally, their life history is characterized by a several-year aquatic larval phase followed by metamorphosis into semi-terrestrial adults. Mount (1975. The Amphibians and Reptiles of Alabama. Univ. Alabama Press. 268 pp.) reported that neoteny was "not uncommon" in *E. cirrigera* in Alabama, and Rose and Bush (1963. Tulane Stud. Zool. 10:121–128) described a form of expedited sexual maturity in *E. aquatica* as it approached metamorphosis, but true paedomorphosis is otherwise unreported in the *E. bislineata* complex until now. Pictured here is a paedomorphic *E. cirrigera* containing 51 ova that was found in Athens, Georgia. Return trips to the site of collection revealed gravid, metamorphosed female *E. cirrigera* and many non-mature larvae of a smaller size, but no additional paeodmorphs.

The cover image was captured by **Todd W. Pierson**, an incoming PhD student to Dr. Ben Fitzpatrick's lab at the University of Tennessee. His research interests largely encompass the ecology, evolution, and conservation of plethodontid salamanders. He currently works in Dr. Travis Glenn's lab at the University of Georgia, where he helps develop genomic and environmental DNA tools.

The cover image is a composite of two photographs taken from directly above and directly below a shallow aquarium suspended off the ground—a photographic style adapted from Danté Fenolio. Dust and scratches in the glass were later removed in Photoshop. The image was recorded using a Canon 7D, 100mm Canon macro lens, and two off-board flashes fired through LumiQuest SoftBoxes. The photograph was captured at ISO 200, 1/200-second shutter speed, and f/20 aperture.

SSAR BUSINESS

Roger Conant Grants-in-Herpetology Program: Guidelines for Proposal Submission

Proposals will be accepted for the 2015 SSAR Roger Conant Grants-in-Herpetology Program starting on 15 September 2014. This program is intended to provide financial support for deserving individuals (with a primary emphasis on student researchers) or organizations involved in herpetological research, education, or conservation.

Important Updates

In Summer 2013, the SSAR Board of Directors allocated additional funds to support this program. As a result, a total of 12 awards, rather than the traditional six awards, will be granted (based on merit) in a given year, starting with the 2014 grant cycle. A new grant category was also approved for the 2014 grant cycle: Undergraduate Research in Herpetology. See the description of this new category below.

Updated criteria and outcomes have been posted for the grant proposals in the Herpetological Education Category. Please see those below.

Reminder: a liability waiver must be submitted with all grant requests. See further details on the SSAR website.

Who Can Apply?

All applicants must be students AND members of SSAR with the following exceptions:

> Those applying for the International category must be students but DO NOT have to be SSAR members.

> Those applying for the Herpetological Education category DO NOT have to be a student or SSAR member.

> Those applying for support of regional herpetological society projects DO NOT have to be SSAR members.

In keeping with the Society's goal of encouraging participation by the broadest possible community of applicants, preference may be given to individuals who might not have access to other funding sources. Applications must be submitted by individuals only (but see special considerations for education categories below).

Grant Amounts and Deadlines

Successful applicants in each of the categories listed below will receive an award in the amount of US $500. It is possible that two grant proposals will receive funding per category if reviewers feel this is warranted. The deadline for submission is 15 December 2014 (see special note on membership dues below). The awards will be announced by May or early June 2015.

Grant Proposal Categories

- ***Conservation of Amphibians and Reptiles.***—Proposals should outline a conservation-oriented research project. This project may focus on species endangered or threatened at the state, national, or international level, or address research on potentially threatened habitats or species, or on introduced injurious species.

- ***The Andrew H. Price Field Research Grant-in-Herpetology.***—Proposals may address needs for field station fees or equipment and materials in field oriented projects, or the field work portions of broader studies. This might include in-situ behavioral studies, ecological, life history, or sexual selection studies. Survey work by individuals or regional societies may be submitted here or in TRAVEL below depending on how the funds are to be used.

- ***Laboratory Research.***—Proposals may address needs for equipment or materials in laboratory projects or laboratory portions of broader projects. This might include studies in behavior, biochemistry, molecular biology, biomechanics, or physiology.

- ***Travel.***—Proposals may address support for travel to field study sites near or far, or to utilize distant collections or facilities. If funding is sought to get from one place to another, proposals should be submitted in the TRAVEL category. Proposals normally submitted in the CONSERVATION or FIELD RESEARCH categories should be submitted here if travel funding is being sought.

- ***International.***—Proposals may address needs in any of the above five categories. The applicant must be a student, but not necessarily a SSAR member. Preference will be given to students with limited access to research funds and in countries where herpetological research has historically been underfunded. Note Regarding Eligibility in the International Category: In 2011, the SSAR Board of Directors decided that proposals in this category would only be accepted if they were submitted from institutions OUTSIDE of the United States. Proposals from students who are primarily affiliated with United States institutions are not eligible for this category.

- ***Herpetological Education.***—Proposals may address an educational project or start up support for an educational program in a zoo, museum, park, nature center, regional herpetological society, etc. The project must focus on a herpetological topic. Note: Although proposals for institutional projects are accepted, education proposals must be submitted by an individual (either sole applicant or principal contact person for the project). Applicants need not be students or SSAR member.

- ***Undergraduate Research in Herpetology.***—Proposals in this category can outline any research project focused on questions related to amphibian or reptile taxonomy, biology, ecology or conservation. Funding can be used to purchase equipment, materials, or as re-imbursement for travel to conduct research (i.e., offset the cost of gas for trips to field sites, museums to investigate specimens, etc.). Applicants must be currently seeking a Bachelor's Degree at an institution of higher learning. Applicants need not be affiliated with US institutions, and international applicants need not be SSAR members. Students that apply for this award must be working directly with a research advisor at an academic or professional institution (i.e., University, Regulatory Agency, Zoological Garden, Museum, etc.). This advisor must submit the letter of support for the student's work. This letter of support must explicitly confirm that the applicant is currently a student and has the time, ability and guidance to successfully complete the proposed project. Strong preference will be given for applicants that have limited funding from other sources.

Additional information and requirements are posted on the SSAR website at: ssarherps.org/pages/GIH.php. All proposals must be submitted electronically to kapferj@uww.edu as a single PDF file named "lastname-category.pdf" no later than 15 December 2014 to be considered (letter of support may be included with the proposal or sent separately). Exceptions to electronic submission and file format may be allowed for special cases with prior approval by SSAR-GIH Chair.
Failure to meet these guidelines may result in elimination of a proposal from consideration.

Successful applicants are encouraged to submit the results of their research for publication in the *Journal of Herpetology* or *Herpetological Review*, and/or to present their findings at the annual meeting of SSAR. Submit proposals or questions regarding application procedures to: Joshua M. Kapfer, Chair, SSAR Grants in Herpetology, Department of Biological Sciences, University of Wisconsin-Whitewater, Whitewater, Wisconsin 53190, USA (e-mail: kapferj@uww.edu).

Grants-in-Herpetology Donor Information

Financial contributions by SSAR members, institutions, and other benefactors support this program significantly, and can increase the number and/or size of awards. Your tax-deductible (for US taxpayers) contribution to this program will directly benefit meritorious research and education in herpetology. Contact the SSAR Treasurer for additional information about contributing to the Grants-in-Herpetology Program. If you are employed by an organization that will match donations made to nonprofit organizations, please notify your employer that you have made a donation to the Grants-in-Herpetology Program.

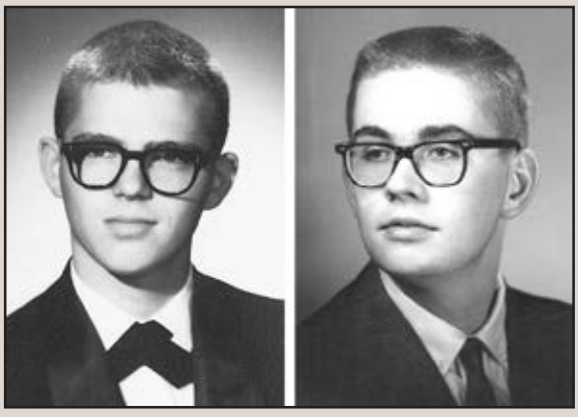
SSAR wishes to thank the many grant reviewers and donors that have instrumental in the success of the Roger Conant Grants-in-Herpetology program for the last several decades. In particular, we would like to thank Tom Beauvais for his generous financial support of this program. We would also like to thank Rebecca Christoffel, whose comments and suggestions greatly improved the guidelines for grant submissions in the Education Category.

Metter Memorial Award, 2014

This year's Dean E. Metter Memorial Award goes to Brenna Forester, a PhD student at Duke University in the Nicholas School of the Environment. Her dissertation advisor is Dean Urban. Forester's proposal is entitled: *Evaluating the Implications of Local Adaptation, Habitat Connectivity, and Gene Flow for Terrestrial Salamanders under Global Change*. She will use molecular techniques to detect adaptation, habitat connectivity, and levels of gene flow in natural populations of the eastern plethodontid

salamanders *Plethodon cinereus* and *P. welleri,* both of which inhabit areas in fragmented and warming habitats. One important general goal of the study is to determine actions that will be effective in conserving salamander biodiversity under a global change regime.

Like many other Metter Award winners, this proposal has clearly identified research questions, developed working hypotheses to test during the course of the research, and involves both laboratory and field work. Congratulations to Brenna!



Proposals for the Metter Award are due on 30 March each year. Information about the Metter Award, including application details, may be found on the SSAR website: ssarherps.org/pages/metter.php.

NEWSNOTES

SSAR Members Elected to American Academy

Among the zoological disciplines, herpetologists are unusually well represented in the American Academy of Arts and Sciences, one of the nation's oldest and most prestigious honorary societies, headquartered in Massachusetts. This spring, in the most recent round of inductions, two more of our most outstanding brethren were selected: **Harry W. Greene** (Cornell University) and **Eric R. Pianka** (University of Texas at Austin). Their careers developed with some striking parallels. They both attended small, private colleges in then relatively unpopulated parts of the country: Texas Wesleyan in Forth Worth and Carleton in Northfield, Minnesota, respectively. Both men became professional ecologists—Harry in behavioral ecology and Eric in population ecology—and today are among our most notable writers of serious natural history. Perhaps most significantly, their interest in reptiles began at a very early age. Both joined the Society in the early 1960s (see photos) when it was still called The Ohio Herpetological Society. As the Society matured and became SSAR, they both published in its principal scientific journal, *Journal of Herpetology.*

Harry, moreover, made a signal contribution to SSAR and to our field when, as a graduate student, he had an idea to publish short natural history notes on herps, and wrote to the then-editor of *Herpetological Review*, Herndon Dowling. SSAR has long prided itself on a willingness to try out good ideas, including those of students and serious amateurs, and the result of Harry's idea is today's "Natural History Notes" section. Still running after more than 40 years, it is now greatly expanded and in full color, and it has been imitated in numerous herpetological journals literally around the world.

Harry Greene (left) and Eric Pianka (right), as budding herpetologists in the early 1960s.

SSAR congratulates Harry and Eric on this great honor, which they have so richly earned for their lifetime of work on the ecology of reptiles.

Haskell Award 2014

PHOTO BY JEFFREY P. BONNER

The Alison Haskell Award for Excellence in Herpetofaunal Conservation is presented by Partners in Amphibian and Reptile Conservation (PARC), in memory of Alison Haskell (1956–2006). This award is intended to recognize an individual from North America who exemplifies extraordinary commitment to herpetofaunal conservation, has thus far been an unsung hero, and has shown exemplary commitment to building or strengthening partnerships.

We are proud to announce that the 2014 recipient of the Alison Haskell Award is **Dr. Jeffrey T. Briggler**. Jeff is currently the Herpetologist / Resource Scientist for the Missouri Department of Conservation. He has an unwavering commitment to hellbender conservation, which involved development of a head-starting and captive propagation program for Ozark Hellbenders at the Saint Louis Zoo as well as creation and design of artificial nest boxes used by hellbenders. Jeff also employed use of regulatory mechanisms, collaboration with land managers, and public outreach to enhance hellbender conservation. His leadership roles, innovative contributions to herpetofaunal conservation, and skill in building effective partnerships make him a very deserving winner of this award. Jeff is not only committed to hellbender conservation, but displays a continued commitment to further conservation of all other herpetofauna throughout the state of Missouri and beyond. SSAR congratulation Jeff on this well-deserved recognition.

EE Williams Research Grant

The Herpetologists' League is pleased to announce competitive grants for graduarte student research for 2015. These awards are named in honor of the late Ernest E. Williams, the first Distinguished Herpetologist of The Herpetologists' League. Awards of up to US $1000 will be presented to one winner in each of the following categories: Behavior, Conservation, Ecology, Physiology, Morphology/Systematics. Full details, including the application form and rules, are available on the HL web site at: http://www.herpetologistsleague.org/dox/eewilliamsgrant.pdf.

Note that the deadline for the 2015 award cycle is 15 December 2014.

Landers Student Research Award

The J. Larry Landers Student Research Award is a Gopher Tortoise Council competitive grant program for undergraduate and graduate students. Proposals can address research concerning Gopher Tortoise biology or other relevant aspects of upland habitat conservation and management. The amount of the award is variable but has averaged approximately US $1,000 per recipient over the last few years.

The proposal should be limited to four pages and include a description of the project, a budget, and a brief résumé of the applicant. This is an excellent opportunity for students to access funding for their project. Awards are typically recognized at the annual meeting to the Gopher Tortoise Council. Deadline for the application is 15 September 2014. Electronic submission is preferred. Please submit proposals to Bob Herrington (e-mail: bob.herrington@gsw.edu).

Reptile Database Update

A new version of the Reptile Database (http://www.reptile-database.org) was released in April 2014. This brings the total to 9952 species (including 30 described this year), up from 9789 noted here in June 2013. There are now 33,558 references (including 281 published this year), up from 31,315 a year ago.

Note that the 30 new species this year were described in 27 papers, of which an astonishing 25 were published in *Zootaxa*. By comparison, the 123 new species of 2013 were described in 90 papers of which only 49 were published in *Zootaxa*.

Selected Taxonomic News and Changes

Subspecies vs species.—In this release we have again elevated a number of subspecies to species level as these new "species" become more widely accepted (hence we have added more species to this release than were described as "new"). Shannon Torstrom and colleagues (2014. Mol. Phylog. Evol. 76:134–143) discussed the impact of genetics and species concepts in their recent paper, "Shedding subspecies: The influence of genetics on reptile subspecies taxonomy." While it is generally accepted that genetics should help to define species boundaries, Torstrom et al. "found that the midpoint genetic distances used for elevation ranged from 1.0% to 19.4%. However, the large difference between the median genetic distances used to elevate a subspecies (6.4%) compared to collapsing a subspecies (1.0%)" shows that genetic differences have been applied on a case-by-case basis rather than by using absolute numbers. Torstrom et al. also remind us that both mammals and birds have about two subspecies per species, a ratio that is dramatically different from reptiles which have less than 0.3 subspecies per species. It is unlikely that this reflects a biological difference but rather a "sociological" or philosophical one. In any case, we will reach the 10,000 species mark later this year. Notably, Australia will reach its own landmark with 1000 species shortly (currently at 996).

Boas and pythons.—Reynolds et al. (2014. Mol. Phylog. Evol. 71:201–213) proposed some signficant changes to the taxonomy of boas and pythons, including a rearrangement of the genera *Bothrochilus, Liasis, Morelia*, and *Sanzinia*. They also described a new genus, *Malayopython* (including *M. reticulatus, M. timoriensis*) and resurrected the genus *Simalia* for *S.*

amethistina, S. boeleni, S. clastolepis, S. kinghorni, S. nauta, S. oenpelliensis, and *S. tracyae*.

Blindsnakes.—Hedges et al. (2014. Carib. Herpetol. 49:1–61) proposed a new classification of the blindsnakes (Typhlopidae), currently containing 258 species. They erected a number of new subfamilies as well as eight new genera: *Indotyphlops, Malayotyphlops, Sundatyphlops, Xerotyphlops, Madatyphlops, Amerotyphlops, Antillotyphlops*, and *Cubatyphlops*. Note that some common species are also affected, e.g., *Ramphotyphlops braminus* has been renamed to *Indotyphlops braminus*.

Turtles.—Iverson et al. (2013. Mol. Phylog. Evol. 69:929–939) erected the genus *Cryptochelys* for a subset of *Kinosternon*. However, Spinks et al. (2014. Mol. Phylog. Evol. 76:254–260) rejected this genus based on phylogenetic gounds and revalidated *Kinosternon* for the six species of *Cryptochelys*.

Thomas et al. (2014. Zootaxa 3786[2]:141–165) described two new species of *Macrochelys*, or rather split up the Alligator Snapping Turtle, *M. temminckii*, into three species. A similar split has been previously suggested by Raymond Hoser although this was rejected by Thomas et al. See the Taxacom mailing list and other online fora for a debate about priority and related issues in this case.

Skinks.—Blair Hedges (2014. Zootaxa 3765[4]:317–338) proposed a new classification of skinks using a system of nine families: Acontidae (26 species), Egerniidae (58), Eugongylidae (418), Lygosomidae (52), Mabuyidae (190), Sphenomorphidae (546), and Scincidae (273) as well as the two new families Ristellidae fam. nov. (14 species) and Ateuchosauridae fam. nov. (2 species). Members of the Ristellidae (*Lankascincus, Ristella*) have been considered as members of the Mabuyidae (or Mabuyinae) while the family Ateuchosauridae is composed of only one genus, *Ateuchosaurus*, previously included in Scincinae/Scincidae. The seven other skink families suggested by Hedges are equivalent to the current skink subfamilies in the Reptile Database (Acontidae = Acontinae, etc.). A survey among skink specialists revealed some skepticism about the new arrangement and recommended to wait for more data to support the two new families, hence we haven't adopted them yet. However, we did make a few adjustments following Hedges as a few genera were still in the wrong (sub-) family, such as *Ablepharus* and *Lobulia* (previously in Sphenomorphinae, now in Eugongylinae). Note that skink taxonomy remains in flux. For instance, the classification used by Pyron et al. (2013. BMC Evol. Biol. 13:93; doi 10.1186/1471-2148-13-93) included only three subfamilies (Acontinae, Lygosominae, Scincinae), with the large subfamily Lygosominae encompassing most of the Sphenomorphinae as currently listed in the database.

Diploglossidae.—We finally implemented the family Diploglossidae as separate from the Anguidae (Anguinae, Gerrhonotinae) as suggested by various authors (e.g., Vidal and Hedges 2009. C. R. Biol. 332:129–139) but as early as 1890 in Bronn's "Klassen und Ordnungen des Thier-Reichs"). The Diploglossidae contain the genera *Celestus, Diploglossus*, and *Ophiodes*.

New Database Features

NCBI database.—The Reptile Database now displays links to the NCBI taxonomy database in its species entries, which lead you directly to GenBank entries. You can find an example at the bottom of *Acanthodactylus blanfordii*. Currently 5039 species have NCBI taxon IDs, a number that will be updated (and thus increase) shortly. Also, in the example you can also see that we have broken out the etymologies of species names into a separate field.

Photos.—We have a large number of new photos (>1500). However, they are added to the database independently of text, and thus have not been updated. This will probably take another few weeks or so, just in case you do not see the photos that you have submitted. Hint: more photos are always welcome.

Global checklist.—An updated global checklist of all reptiles with their higher taxa is now available as an Excel spreadsheet: http://www.reptile-database.org/data/reptile_checklist_2014_04.xls.zip

Database downloads.—You can now download older versions of the database as tab-delimited text files from Figshare (via our Download page, <http://www.reptile-database.org//data/>). Only a few older versions from 2008–2010 are currently available but more recent ones will follow shortly. These archives may come in handy if publications have cited older versions of the Reptile Database and you try to reproduce their results.

Other Notable Recent Publications

Reptile pet trade statistics.—Herrel and van der Meijden (2014. Herpetol. J. 24[2]:103–110) just published an interesting analysis of the reptile and amphibian trade in the USA and other parts of the world. They found that an average of 7 million individual animals have been imported into the US from 2001 to 2008 while an average of 14 million individuals have been exported during the same time. Of the top-exported species, *Trachemys scripta*, 48 million individuals were exported by the US from 2001 to 2009. For some popular species, captive-bred specimens provide the majority of individuals (e.g., *Iguana iguana*) but for others (such as *Python regius*) the vast majority are from the wild. Another study arrives at somewhat different estimates for exported turtles from the US; Mali et al. (2014. PLoS ONE 9[1]:e86478) estimate that the two top-exporting states (Louisiana and California) exported about 10 million turtles per year from 2002 to 2013.

More details on changed names, etc. are listed on our news page: http://www.reptile-database.org/db-info/news.html.

© 2014 by Society for the Study of Amphibians and Reptiles

Dr. rer. nat. Uwe Norbert Hiller (1942–2008): Pioneer of Experimental Investigation of the Molecular Basis of Adhesion in Geckos

Although expressed in relation to issues of public health and insect control, rather than adhesive capabilities, Loveridge (1947) noted that, "It is probable that we are only on the threshold of discovering the importance of geckos to mankind." That prophetic utterance was made when Uwe Hiller was five years old. By the time of Uwe's death in 2008, geckos had become a major focus of research, not only in the context of their own fascinating biology, but also as inspiration for biomimetic and bioengineering applications. Now physicists, chemists, computer scientists, and engineers, as well as biologists, are avidly studying these diverse lizards with an eye to revealing the secrets of their phenomenal clinging abilities, and to adapting the underlying principles to a wide array of perceived applications. Such efforts have, at their heart, the elucidation of the mechanisms, at the molecular level, that permit geckos to stick to surfaces, using their keratinous setal arrays carried on the underside of their digits. As Henkel and Schmidt (1995) noted, "Mankind has always been fascinated by this ability" and there have been many attempts to determine how such a mechanism operates. Uwe Hiller played a major, if relatively brief, role in solving these mysteries and in paving the way to making this modern research bonanza possible.

often lagged behind theory, largely as a result of a lack of appropriate technology that could be applied to the problem. Although the presence of setae, the ultimate agents of adhesion, had been established relatively early (Cartier 1872), their structure, morphology, and composition was not particularly well understood until almost one hundred years later. With the advent of scanning electron microscopy, studies of setal morphology (Ruibal and Ernst 1965) and elucidation of the details of their hierarchical structure (Maderson 1964, 1966) led to new theories about the ways in which they may function. This tantalizing backdrop provided Uwe Hiller, a physics-minded herpetologist, the opportunity to move these studies in new and exciting directions.

Born on 23 August 1942 in Hopfental, Germany, Uwe Hiller attended School in Hagen (northern Westfalia), and matriculated from high school [*Abitur*] in 1963. He studied biology at the *Westf. Wilhelms-Universität Münster*, and completed his PhD. dissertation in the *Zoologisches Institut* of that institution. Its title was: "*Untersuchungen zum Feinbau und zur Funktion der Haftborsten von Reptilien*" [Investigations of the detailed structure and function of the adhesive setae of reptiles]. His doctoral examination was held on 3 May 1968 and his specialization subjects were Zoology, Botany, and Inorganic Chemistry. The findings of his PhD investigations were published, in German, very shortly thereafter (Hiller 1968).

The seminal contributions that Uwe Hiller made to advancing the theory and experimental observation of gecko adhesion were undertaken when this subject seemed to reside purely within the domain of curiosity-driven research. Dr. Hiller will be remembered, above all, for conducting the first modern, and carefully controlled, experiments on the role of molecular forces in gecko clinging. Following in the footsteps of a line of German researchers who had made major contributions to elucidating this phenomenon (Cartier 1872; Haase 1900; Weitlaner 1902; Tandler 1903; Schmidt 1904, 1912; Dellit 1934), Uwe was introduced to the topic by his PhD advisor, Dr. Rudolf Altevogt. Altevogt, whose main academic interests focused upon the physiology and ecology of crabs, published a short review article in *Kosmos* (Altevogt 1954) entitled *Probleme eines Fußes*, his only contribution to the phenomenon of gecko adhesion. In that brief article he indicated that new technologies were making novel approaches possible, and published what is likely the first scanning electron micrograph of gecko setae (Altevogt 1954: fig. 3). The species studied in that paper was *Tarentola mauritanica* (the Moorish Gecko), and it was this same species that served as the subject of the majority of Hiller's (1968, 1969a, 1970, 1972) pioneering investigations into the basis of gecko adhesion. Hiller (2000) summarized his contributions to this area, but essentially published no more experimental work on gecko adhesion after the early 1970s.

Uwe Hiller was inspired by the work of Haase (1900), who had first suggested that molecularly-based adhesion forces were responsible for clinging in geckos. Until the 1960s there were no practical ways to test this theory. Uwe was able to exploit new technologies to investigate Haase's (1900) hypotheses. In doing so, he explored the physical nature of surface forces, basing this on recent work on the concept of free surface energy and the molecular polarity of surfaces, and found ways of measuring and manipulating the surface energy of specific substrata (polytetrafluoroethylene films) and of recording the clinging ability of geckos under varying free surface energy conditions. Hiller's (1968, 1969a) experiments revealed that a gecko's ability to adhere was directly related to the surface energy of the substrate, as measured by its water contact angle. He discovered that setae could stick to hydrophilic surfaces (those with a low water contact angle), but were less capable of adhering to hydrophobic surfaces (those with a high water contact angle). This suggested that the adhesive force generated by setae increases with increasing surface energy. Based on this, Hiller (1968, 1969a, 2000) concluded that attachment in geckos occurs by way of intermolecular forces, although he was not able to conclusively determine which type of intermolecular forces dominated.

These explanations remained the most compelling for the understanding of these phenomena for the following 30 years, until the next great technological advances were made, using microelectromechanical sensors (Autumn et al. 2000, 2002; Autumn and Peattie 2002) and newly available and highly controllable materials (Autumn 2006). Through measurement of attachment forces generated by individual setae, it was found that these were consistent with the forces expected to be produced by intermolecular attachment via van der Waals forces, and were inconsistent with other possible mechanisms of attachment, including suction, friction, and micro-interlocking (Autumn et al. 2000). The potential differential ability of setae to attach to hydrophilic versus hydrophobic surfaces was refuted, with Hiller's (1968, 1969a) observations relating to this being attributed to the experimental conditions rather than preferential capability. Later the importance of certain types of frictional forces in attachment were also reassessed (Autumn et al. 2006; Tian et al. 2006). These more recent findings led to the explosion of interest in gecko adhesion that pervades the literature today, but they are firmly founded on Uwe Hiller's insightful studies. Because most of Dr. Hiller's work on this subject was published in German, it is not as well known as it might otherwise have become.

Following his PhD, Uwe Hiller was quickly hired (his position began on 1 June 1968) by Prof. Dr. Rudolf Altevogt, as a technical assistant at the *Zoologisches Institut* in the department of Zoophysiology and Ecology. During his time in Dr. Altevogt's laboratory his research was very productive and he continued to work on gecko adhesion along with venturing into the integumentary sensory mechanisms associated with modulating attachment. He worked in Dr. Altevogt's group until 30 September 1980, at which time he moved to the *Institut für Anatomie der Westf. Wilhelms-Universität Münster*, to join the group of Prof. Dr. Hans-Jost Dieterich as a scientific assistant. Dr. Dieterich's group focused on human anatomy. He was hired specifically for his skills

in scanning electron microscopy. This position provided Uwe with greater academic opportunities and he was able to teach as well as conduct his technical duties.

Associated with this change of position came a hiatus in the output of Uwe's curiosity-driven research. From the late 1970s to the early 1990s he published relatively little related to his own agenda, and during this time his research focus shifted. He was afforded the opportunity to prepare a *Habilitationsschrift*, and for this worked on the eyelids and conjunctive membranes of reptiles. In 1992 he completed his habilitation thesis, "*Die Augenlider und Membrana nictitans der Reptilien*," but was not invited to defend his work at a formal oral examination because the reviews from his external examiners were mixed. In the face of this potential setback, Uwe decided to opt for occupational security rather than continue the pursuit of a professorship, and thus never formally undertook his habilitation examination.

Many of his major herpetological contributions thus proceeded from his PhD work and from his still-born habilitation thesis. He was driven by a curiosity about how animals worked, and was fascinated by structural mechanisms, a trait also reflected in one of his hobbies, watchmaking and horology, for which he maintained a workshop in the basement of his home. He continued to work in his technical position in Dr. Dieterich's group until his retirement on 31 August 2007, at the age of 65. Uwe Hiller thus spent his entire academic career (as undergraduate student, graduate student, and technicial assistant) at the same institution.

For his herpetological contributions, Uwe Hiller seldom strayed far from aspects of the integument, and employed his expertise with SEM to investigate various anatomical problems. Fascinated by how the adhesive mechanism was controlled and how contact with the surface was modulated, he ventured into conducting anatomical and physiological studies of the cutaneous sensilla of reptiles (Hiller 1971, 1976a, 1976b, 1976c, 1977, 1978).

His explorations of various aspects of eye anatomy (Hiller and Dieterich 1986; Dieterich et al. 1988; Hiller 1995, 1998) had their foundations in the research conducted for his ultimately unfulfilled habilitation thesis. At the time of his death he had developed collaborative partnerships to pursue this further, and was working on a major synthesis of what is known about the form and function of reptilian eyelids and their associated glands with Susan Rehorek and Yehudah Werner.

Sometimes happenstance led to new and intriguing studies. While one of us (YLW) was investigating foraging modes in geckos, individuals were marked with adhesive tags to facilitate observations. For introduced populations of *Phelsuma* in Hawai'i, it was found that the adhesive tags, able to be successfully applied to all other geckos investigated, would not stick. Uwe was consulted for his knowledge of squamate skin structure, and this investigation led to the discovery of unicellular skin glands in *Phelsuma* (Hiller and Werner 2008).

His last two published contributions were made in areas that are very topical, the water repellence of gecko skin (Hiller 2009) and feather regeneration in birds (Maderson et al. 2009). Scattered through his publishing career were technical and clinical contributions that focused on methodology (e.g., Hiller and Blacksche 1968; Hiller, 1969b) and on applications related to his work in Dr. Dieterich's group (e.g., König et al. 1987, 1993). He was very respectful of amateurs keen on reptiles, and cooperated with them to encourage their interests. Uwe Hiller enjoyed attending conferences and presenting his work, and was able to communicate widely at European meetings because of his fluency in German, English, and Spanish (as well as Latin!). One presentation that gave him particular satisfaction was delivered in 1993 at the Hebrew University, Jerusalem. On this occasion Uwe spoke in English to a general audience, captivating them with his knowledge and demonstration of gecko adhesion, and using a Teflon®-coated frying pan to reveal the limits of the adhesive capabilities of these lizards. The reason for the satisfaction was that Uwe's father had resisted the policies of the Third Reich in Germany, and this presentation provided Uwe with the occasion to honor that family legacy.

Uwe Hiller died suddenly on 8 Spetember 2008 in Münster, Germany. He is survived by his wife, Karola, three children, Barbara, Martin, and Norbert, and five grandchildren. To those who visited him to conduct collaborative research (including one of us, YLW), Uwe was a welcoming and caring host who willingly made space available in his own home for visitors. There they were able to enjoy Uwe and Karola's passion for gardening, and to partake of the wine Uwe made, often produced from grapes grown in the conservatory attached to their house, a structure also known for its resident population of Moorish Geckos. At the end of a busy day, visitors were also encouraged to join the Hillers in watching a "*Krimmi*," a slang term referring to the German detective story movie genre.

Acknowledgments.—We are indebted to Dr. med. Reinhard Hildebrand, director of the *Institut für Anatomie der Westf. Wilhelms-Universität Münster* at the time that Uwe Hiller was working there, for providing biographical details gleaned from his employment file, and to Karola and Barbara Hiller for providing family and personal information and photographs.

CURRENT RESEARCH

The purpose of Current Research is to present brief summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editors, Jesse Grismer or Ben Lowe; e-mail addresses may be found on the inside front cover.

Reassessment of Crocodilian Species Diversity in Africa

In 2011, a cryptic species of African crocodile, *Crocodylus suchus*, was revealed with the aid of molecular data, indicating that other cryptic species might have been overlooked. To further elucidate African crocodile diversity, Shirley et al. report their findings from an investigation into the morphological and genetic diversity of the Slender-snouted Crocodile, *Mecistops* (formerly *Crocodylus*) *cataphractus*, a species distributed across tropical West and Central Africa. Genetic samples were accumulated from across the species' distribution, and eleven genes were sequenced. These data were incorporated into an analysis employing recently developed Bayesian species delimitation methods (BP&P), as well as other genetic clustering analyses that have previously been used to identify crocodilian species. These analyses offered categorical support for *Mecistops* comprising two parapatric species, one including populations in the West African countries Côte d'Ivoire, Ghana, and the Gambia, and one consisting of populations spanning Central Africa. An exhaustive morphological analysis of 91 *Mecistops* skulls found 13 characters that in combination serve to differentiate the two species, including two for which each species exhibits a fixed difference. These diagnostic characters and the results of a multidimensional scaling analysis allowed the researchers to interpolate the species' ranges where molecular sampling was lacking. Importantly, skulls from Nigeria were identifiable as the western

species while Cameroon samples fell out with the eastern species, suggesting a possible geographic feature separating these two species—the Cameroon Volcanic Line (CVL), a mountainous and geologically active plateau that runs perpendicular to the coast. A fossil-calibrated phylogeny including all recognized crocodilian species places the split between the two *Mecistops* species somewhere between five and ten million years ago. Interestingly, this estimate is temporally congruent with the split inferred for the two previously identified lineages of West African Dwarf Crocodile (*Osteolaemus tetraspis*). The *O. tetraspis* split may also be coincident with the CVL; unfortunately, conserved morphology precludes inferring clade membership of Nigerian *Osteolaemus*. The CVL has long been recognized as an important biogeographic feature for montane organisms, and this study suggests this may be true for lowland taxa as well. This study also highlights regions of conservation priority in West Africa.

Lungless Salamanders Thermoregulate Behaviorally

Salamanders have long served as textbook examples of thermoconformers, organisms that use neither metabolic activity nor behavior to modify their body temperatures and instead passively reflect the temperature of their environment. However, common sense indicates there are limits to this—many amphibian species incapable of surviving freezing temperatures nevertheless live in regions that experience freezing winter temperatures. Furthermore, laboratory studies have shown that plethodontid salamanders actively choose optimal temperatures. To investigate this phenomenon in nature, the authors of this study gathered data on two North American plethodontids (*Plethodon glutinosus*, *Eurycea lucifuga*) in the laboratory and in nature. These species are frequently associated with caves (but lack troglobitic characteristics such as reduced eyes and pigmentation) and only distantly related, offering an interesting opportunity to test hypotheses regarding thermal ecology. The authors attempted to survey six caves in northwestern Georgia every spring, summer, and fall for 13 years. Specifically, the researchers surveyed for salamanders outside and far enough into the caves where external climate had limited influence (the twilight zone), and took temperature readings at these points. Representatives of these species were also brought into the laboratory and subjected to trials where they were offered a gradient of temperatures ranging from 10 to 40°C. Finally, locality data for these species were gleaned from museum records, and with temperature, precipitation, and land cover data, ecological niche modeling analyses were conducted to evaluate whether the distributions of these species are defined by different abiotic variables. Consistent across all caves, the twilight zones were always cooler than the area outside, with the greatest temperature differential occurring in the summer. Densities within the caves fluctuated seasonally for both species, with *P. glutinosus* reaching maximum density in the summer and *E. lucifuga* being most abundant in the spring and fall (while *P. glutinosus* is presumably outside the cave). This finding suggests *E. lucifuga* has a lower preferred temperature than *P. glutinosus*, and the laboratory trials confirmed this. The niche modeling exercise showed the factors limiting *P. glutinosus* distribution involve moisture, while five of the six most important variables for *E. lucifuga* pertained to temperature. While the abiotic variables predicted the distribution of *E. lucifuga* with high precision, they overpredicted the range of *P. glutinosus*, suggesting biotic interactions may be important in limiting the range of this species. Taken together, these findings show that these species move around in response to temperature fluctuations, and therefore thermoregulate through behavioral means.

Snake Spectacles Modulate Blood Flow to Minimize Obstruction of Vision

In lieu of eyelids, snakes and several other squamate lineages possess a clear structure called a spectacle over their eyes. This structure is similar to the vertebrate cornea (which snakes also have), but unlike a typical cornea, the spectacle contains blood vessels. These vessels are transparent, but the blood is not and likely obscures vision. The authors of this paper conducted a study of snake spectacle vascular physiology to identify adaptations that mitigate potentially impaired vision. The spectacles of snakes were observed with near-infrared (NIR) light and a NIR-sensitive video camera capable of resolving individual blood cells. Three Coachwhips (*Coluber* [= *Masticophis*] *flagellum*) a diurnal, visually oriented species, were subjected to seven trials each, wherein an eye was recorded for 70 minutes. The trials employed the following protocol: 30 minutes undisturbed, eight minutes of threat (experimenter moving in the vicinity of the snake), 16 minutes undisturbed, eight minutes of threat, eight minutes undisturbed. Snakes were not tested when their spectacles were clouded due to an impending shed, as preliminary observations revealed that during shed preparation, blood flows continuously across the spectacle. Statistical analysis (ANOVA) of the trial data revealed that when at rest and undisturbed, the flow of blood across snake spectacles is discontinuous, alternating between short periods of flow and long periods of no flow. When snakes detect a potential threat, the duration of the flow periods is reduced further, allowing unperturbed vision. Within trials, patterns of flow did not change between the two threat episodes, indicating threat habituation was not occurring. Though they could not make out the translucent capillaries, the authors posit that capillary constriction is responsible for flow cessation. They also suggest future studies should examine the vascular dynamics of other spectacled squamates and whether vascular responses to a perceived threat are simultaneously occurring in other parts of the dermis.

Blue Tails Elicit Attacks from Potential Predators

Aposematism, the presence of conspicuous colors or patterns on an organism that grab the attention of the viewer, is a feature seen in many species of reptiles and amphibians. Often, aposematism serves to alert a potential predator to an otherwise hidden defense (such as a toxin). However, different lizard lineages have independently evolved brightly colored tails, presumably serving to draw a predator's attention to the tail. Most lizards with aposematic tails have the ability to autotomize their tail, and therefore attracting predators to the tail facilitates escape. For those that do not exhibit tail autotomy, an attack to the tail is less life-threatening than an attack to the body or head. To test the hypothesis that aposematic tails serve to attract attacks, the authors of this study made clay models with brown bodies, half with blue tails (aposematic) and the other half with brown tails (non-aposematic), and placed them in the field at the Archbold Biological Station, Florida, USA. These models approximated the Southeastern Five-lined Skinks (*Plestiodon inexpectatus*), a common species at the site. Models were checked daily and scored for predation attempts (rodent vs. bird, location on body of attack). In all, 65 attempted predation events were observed, 92.3% of which could be attributed to birds (likely Florida Scrub Jays, *Aphelocoma coerulescens*). Analysis revealed that the aposematic models received more predation attempts than the non-aposematic models. Furthermore, the proportion of attacks aimed at the tail was significantly higher for the aposematic models. Indeed, most attacks on the non-aposematic models were directed at the head or body, while those on the aposematic models were most frequently aimed at the tail. These findings support the hypothesis that at least in this system, aposematic tails are "risky decoys" that serve to draw attacks to the tail, not discourage potential predators from attacking. The authors hint that the ontogenic change in tail color seen in many of these lizard species reflects foraging style divergence between juveniles and adults.

New Estimate of Origin of Lepidosauria

Recent fossil discoveries and advances in phylogenetics have provided an unprecedented understanding of the history of life on earth. Unfortunately, precise estimates of the timing of Lepidosauria (squamates and rhynchocephalians) origin and diversification have remained elusive. This is due in part to the paucity of early crown lepidosaur fossils. The authors of this paper describe a recently unearthed, 240 million years old (Middle Triassic) fossil rhynchocephalian from the vicinity of Vellberg in southern Germany. This new fossil predates the next oldest lepidosaur fossil by twelve million years. The material consists of two dentaries that exhibit distinctively rhynchocephalian features and closely resemble those of a previously described, younger rhynchocephalian, *Diphydontosaurus*. Morphological phylogenetic analyses corroborate this assignment. Along with other known reptile fossils, the authors incorporated this new fossil as a calibration point in a time-calibrated molecular phylogenetic analysis of nuclear DNA sequence data for *Sphenodon punctatus*, 65 squamate taxa, and eleven outgroup taxa. While previous analyses have placed the origin of Lepidosauria in the Permian, these analyses yield a younger date of 242 million years (range: 238–249.5; Early to Middle Triassic). This finding suggests Lepidosauria diversification occurred subsequent to the Permian extinction event. Furthermore, these analyses find Squamata diversification occurred in the Jurassic in the wake of an extinction event that occurred at the end of the Triassic. These dates suggest these groups may have diversified as they filled vacated niches. The authors contend that this fossil bed spans an important time in the history of life on earth, and that it may hold additional important finds.

Suction-Feeding Turtle Unearthed in Morocco

While suction feeding has evolved in most lineages of marine vertebrates, turtles have been considered an exception. This is remarkable, as suction feeding has evolved independently in two freshwater testudine lineages (Chelidae and Chelydridae). The authors of this paper announce the discovery of a new, apparently suction-feeding turtle from Morocco. They erect a new genus for this turtle and name it *Ocepechelon bouyai*. The fossil bed contains marine fauna and dates to the Maastrichtian, the last age of the Mesozoic. The material consists of one complete skull (no mandible) 70 cm long, ranking among the largest turtle skulls ever recorded. Strikingly, the snout is narrow and tubular, the external nares are positioned dorsally and far back from the anterior margin of the snout (just anterior to the bony orbits), and shearing, crushing, and prey-manipulation structures are lacking. The morphology of the hyoid is not known, though this would serve as a good indicator of feeding strategy. However, the pterygoid possesses large ventral plates and the squamosals flare out laterally in dramatic fashion, providing large attachment surfaces for the musculature required for suction feeding. Together these findings strongly suggest *O. bouyai* was a small-gape suction feeder, similar to living beaked whales and syngnathid fishes (seahorses, etc.). A phylogenetic analysis of a morphological dataset places *O. bouyai* in Dermochelyoidae, a clade that contains several extinct taxa as well as the Leatherback Turtle (*Dermochelys coriacea*) and is sister to the family Cheloniidae. The authors speculate that like *Dermochelys*, *O. bouyai* may have possessed

buccopharyngeal papillae that would have allowed excess water to escape while maintaining prey items. This study adds to our understanding of phylogenetic and morphological diversity of marine reptiles at the close of the Mesozoic.

Bardet, N., N.-E. Jalil, F. de Lapparent de Broin, D. Germain, O. Lambert, and M. Amaghzaz. 2013. A giant chelonioid turtle from the Late Cretaceous of Morocco with a suction feeding apparatus unique among tetrapods. PLoS ONE 8: e63586.

Famous Frog-Jumping Competition Lends Insights into Estimating Performance

California's annual Calavaras County Fair and Jumping Frog Jubilee features a world-famous frog-jump competition, inspired by an 1865 short story by Mark Twain. In this festival, held in the town of Angel's Camp in the foothills of the Sierra Nevada, causal visitors and competitive hobbyists alike enter frogs into contests, with the winners being those whose frog manages the most prodigious leap. Visitors are allowed to "rent" frogs for these contests (these days, American Bullfrogs, *Lithobates catesbeiana*). The authors of this paper decided this event would be a great opportunity to collect data that could be used to evaluate our ability to estimate a species' maximum capacity for some act, which in this case was a single leap. In 2012, they attended the festival and recorded jumping trials, from which distance measurements were extracted. In the competition, the first three jumps are recorded, and the researchers collected jump-distance data for these and any subsequent jumps. From these data, the researchers generated histograms of jump distance, and used t-tests to determine if there was a jump-distance difference between rented and hobbyist-supplied ("pro") frogs. Overall, 3124 jumps were recorded, investigations of which revealed that most jump measurements exceeded the maximum published distance for *L. catesbeiana* (1.295 m), and the longest distance they recorded was 2.2 m. The distance jumped differed significantly between rented and pro frogs, with pro frog jumps averaging 0.4 m longer than those of rented frogs, indicating either the competitive hobbyists were actively selecting the most prodigious jumpers or their technique for prompting a jump was superior. Interestingly, while the distances jumped by rental frogs were normally distributed, the pro frog jumps were skewed toward short jumps, indicating that the longer jumps were likely approaching a real performance limit. Even with the left-skewed distribution, subsampling of the data revealed that large sample sizes are necessary for consistently observing maximum jump distances. This finding is certainly germane to researchers studying physical performance.

Pelagic Sea Snakes Tolerate Drought in a Dehydrated State

The pelagic Yellow-bellied Seasnake, *Hydrophis* (formerly *Pelamis*) *platurus* is the most widely distributed squamate, occurring from Africa's east coast, across the temperate and tropical stretches of the Indian and Pacific Oceans, to the west coasts of the Americas. This remarkable distribution is a consequence of this species adopting a pelagic lifestyle, not found in other sea snakes. Nevertheless, like all snakes, *H. platurus* require fresh water to stay hydrated. The primary source of fresh water in the open ocean is a thin freshwater film that exists on the ocean surface following rain, the frequency of which fluctuates with the seasons. To determine if these snakes survive dry periods with an unusual tolerance of dehydration, the authors of this paper collected in excess of 500 snakes from the vicinity of Golfo de Papagayo, northwestern Guanacaste, Costa Rica. These snakes were brought into the lab and evaluated for body condition (weight relative to length) and willingness to drink fresh water. Those that drank water were subsequently weighed to calculate the volume of water consumed. Furthermore, twenty snakes collected at the end of the dry season and 20 collected at the end of the wet season were desiccated in an oven after death or euthanasia to determine water content. These experiments demonstrated that *H. platurus* do indeed experience considerable dehydration during dry spells. Snakes caught after a significant dry period and/or exhibiting poor body condition were more likely to drink, and the quantity of water drunk was inversely proportional to body condition. Total water content of the snakes was significantly lower at the end of the dry season than at the end of the wet season. The percent water content of hydrated *H. platurus* (~80%) is considerably higher than recorded for other snakes (69-77%) and sea turtles (64-66%), indicating a possible adaptation for dealing with droughts. These studies indicate that sea snakes experience wide fluctuations in water content across seasonal changes, and are able to tolerate severe states of dehydration.

Ambystoma Salamander Found with Developing Eggs in its Oviduct

Amphibians exhibit diverse reproductive strategies, including egg-laying and live birth, internal and external fertilization, and direct development and metamorphosis from a larva. Despite this diversity, it has been assumed that for all egg-laying species that practice internal fertilization, fertilization occurs immediately prior to egg laying. The authors of this paper report an observation of an *Ambystoma* salamander in Massachusetts, USA, with fertilized eggs containing partially-developed embryos in its oviduct. The salamander was encountered deceased on the road during the spring migration. DNA sequence data from the salamander revealed it to be a unisexual triploid (LJJ genotype), which are common at the site. Despite being unisexual,

these salamanders require sperm from a male of one of the parental species to initiate egg development (in this process, the sperm does not contribute genetic material). The eggs were investigated using florescent microscopy and were revealed to be approaching or undergoing gastrulation (developmental stage 10). Given the air temperature and our understanding of *Ambystoma* embryological development, the authors posit that the eggs had been developing for two or three days, long before the salamander met its demise and probably before it initiated its reproductive migration. They suggest development was likely initiated in the absence of sperm or with the assistance of stored sperm. This discovery adds to the list of fascinating reproductive biology exhibited by amphibians.

River-Dwelling Painted Turtles Not Affected by Extreme Flooding

With climate change threatening more dramatic and more frequent weather events, understanding how species cope with extreme weather scenarios is critically important. To investigate how different spring flooding scenarios affect Painted Turtle (Emydidae: *Chrysemys picta*) populations in the American Midwest, the authors of this study collected 16 years of mark-recapture data for females belonging to a Mississippi River population. During this time the site experienced four intense flooding events, where water levels were two meters higher and flow rates were as much as six times greater than in non-flood years. Analyses of these data did not recover a significant effect of flood intensity on survivorship, recruitment, detectability or population growth. Indeed, the only period where a population decline was observed was during an unusually long stretch without significant flooding (2003–2008). The authors suggest that this species may have behavioral adaptations that mitigate the potential effects of intense flooding events, despite being more typically associated with ponds and lakes which do not experience such floods. They also caution that their findings have little bearing on the effects of flooding on male and juvenile Painted Turtles or the species' resilience to other severe weather events such as heat waves or flooding outside of the spring season.

Salamander Size Reduction Linked to Climate Change

The southern Appalachian Mountains are a center of diversity for salamanders of the family Plethodontidae. As montane plethodontid salamanders are limited in their capacity for niche evolution and tracking suitable climates, they are expected to suffer disproportionate affects due to climate change. One hypothesized consequence of climate change is a change in body size due to an altered energy budget. To determine if the effects of climate change are already apparent, the authors of this paper surveyed for and collected morphometric data from 15 *Plethodon* species along the main axis of the southern Appalachian Mountains from Maryland through Tennessee and North Carolina. Importantly, they collected data from 64 sites from which *Plethodon* have been collected at various times across the second half of the 20th century. Together with measurements from historically collected specimens, the authors fit linear models to the data with the purpose of identifying shifts in body size across the study period. These analyses revealed a statistically significant 8% reduction in body size averaged across the fifteen species; this finding remained significant even when the contemporary measurements of live salamanders were removed. Of the fifteen species investigated, six showed significant reductions in size while one species increased in size across the study period. Several possible correlates of body size reduction were evaluated, and the best predictor was found to be latitude. The authors suggest this can be explained by the lower latitudes having experienced disproportionate increases in temperature and decreases in precipitation, and those two phenomena are driving changes in energy expenditure. To test this, they modeled activity time and metabolic energy expenditure for three latitudinally distinct sites and found that while annual activity time has not changed appreciably across the study period, energy expenditure has increased significantly, providing a mechanism for body size reduction. The authors suggest that future research could reveal whether their findings represent a plastic response to increased energy costs or selection acting on body size.

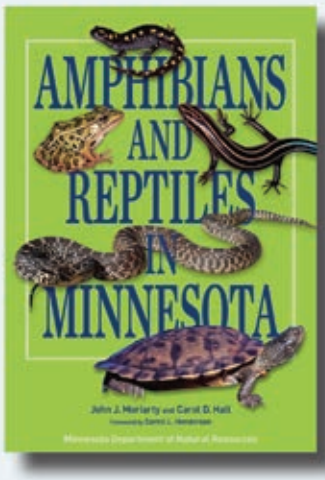
Photos Solicited for the New Show

HERPETOLOGISTS PAST AND PRESENT

For those who don't recognize Joe Mendelson (here in a more serious moment), he was SSAR President in 2011–2012.



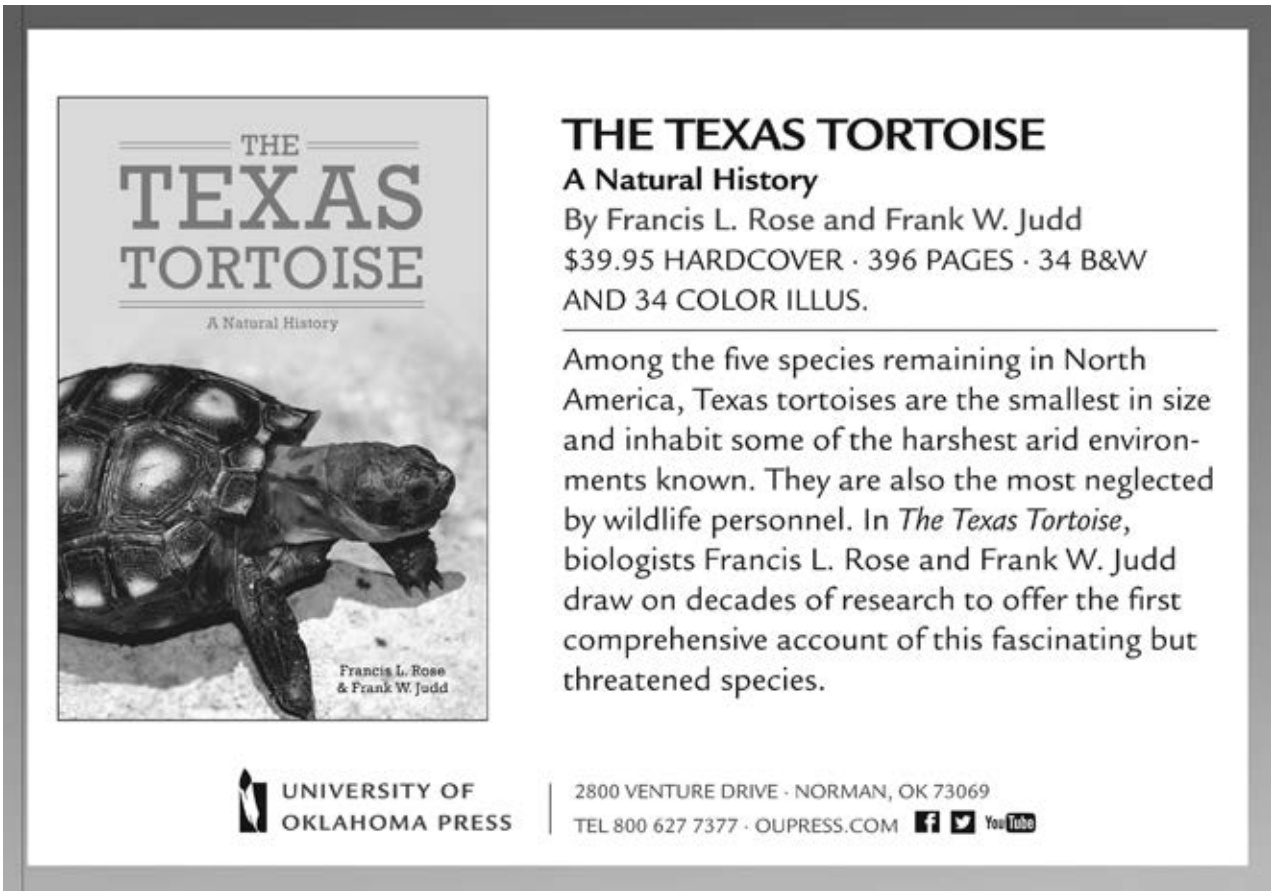
PHOTOGRAPH BY ALISON KELLY

To Be Revised for University of Kansas Meeting in 2015
See meeting notice in *Herp. Review*, March 2014, p. 192.

In 1982, SSAR commissioned an audiovisual slide show to celebrate its 25th Anniversary Meeting in Raleigh (North Carolina). This 30-minute program was later enlarged and became a popular staple at SSAR meetings for nearly two decades. However, the technology used then (6 computer-controlled slide projectors) is now obsolete and must be completely revised using modern digital techniques.

SSAR has commissioned a new program, to debut at its 2015 meeting at the University of Kansas (July 30th through August 3rd). Color slides of herpetologists at work or play are hereby solicited. These may be color slides (which will be returned after scanning) or digital files (at 300 dpi/ppi or higher, preferably in TIFF but JPEGs are OK; best to burn files to CDs or DVDs). *All sources will remain confidential!*

Please send all of your images to David M. Dennis, 2708 Bigelow Drive, Sarasota, Florida 34239, USA or send them by e-mail to daviddennis@verizon.net. Be sure to include relevant data for each image (names of persons, dates, places, etc.).



The most complete and up-to-date guide to Minnesota's reptiles and amphibians

Including current information about designations of species in need of conservation, this reference covers the latest research and work on environmental threats and amphibian and reptile protection, such as the deformed frog phenomenon, turtle legislation, climate change, and habitat restoration.

More than 250 color photos

University of Minnesota Press
www.upress.umn.edu | 800-621-2736

Cover Images for *Herpetological Review*

We are looking for photographic images to appear on future covers of *HR*. To be considered, preferred images should have the following qualities:

- Should be technically superior photographs (e.g., composition, lighting, etc., should be excellent; subject must be in focus).
- Should be taken in vertical format, or, if in landscape format, permit cropping to achieve a vertical orientation (2550 × 3300 ppi).
- Should be based on film or digital media; if the latter, the native resolution must be sufficiently high to permit cropping and/or enlargement to print publication quality.
- Preference will be given to images that depict poorly known species. These could include recently described taxa or species for which a color illustration has never been published.
- Preference will be given to images that communicate some aspect of the biology of the organism (e.g., predation, feeding, courtship, crypsis).
- Images should not have been published previously nor concurrently submitted for publication elsewhere (print or electronic media).

Images for consideration should be submitted as low-resolution jpg or pdf files. Do not send full resolution images unless requested to do so. All submissions or questions should be directed to the Editor (herpreview@gmail.com).

INFORMATION FOR CONTRIBUTORS

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes concerning the study of amphibians and reptiles, as well as book reviews, commentaries, regional and international herpetological society news, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (for information, please refer to: http://www.ssarherps.org/pages/JHinstr.php). To submit a manuscript to ***HR***, please consult the SSAR webpage at:

<http://www.ssarherps.org/pages/HRinfo.php>

REPRINTS AND PAGE PROOFS

Page proofs are sent electronically to authors of all articles, book reviews, and obituaries, but are not prepared for natural history, geographic distribution, or herpetoculture notes. Proofs are sent as pdf files approximately 2–4 weeks prior to publication. High resolution electronic (pdf) reprints of notes, articles, book reviews, and obituaries are provided at no charge to the primary/corresponding author as a benefit of SSAR membership. Reprint files will normally be sent prior to the issue mailing date from the printer. Authors who are not current SSAR members may purchase pdf reprints from the SSAR Publications Office.

ADVERTISING

Herpetological Review accepts commercial advertising. Rates and copy information are available from the SSAR web page (http://www.ssarherps.org/pages/HRinfo.php).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at the Department of Natural Sciences, Williams Baptist College, P.O. Box 3692, Walnut Ridge, AR 72476, USA. Periodicals postage paid at Walnut Ridge, AR 72476 and at additional mailing offices.

All rights reserved. No part of this periodical may be reproduced without written permission of the Editor, except that authors and their agents are permitted to reproduce and distribute their own articles and notes.

POSTMASTER: Send address changes to Breck Bartholomew, SSAR Publications Secretary, P.O. Box 58517, Salt Lake City, UT 84158. **MISSING OR DAMAGED ISSUE?** Please notify Breck Bartholomew, SSAR Publications Secretary (e-mail: ssar@herplit.com) for a replacement.

SSAR PUBLICATIONS

SSAR publishes seven different series: *Journal of Herpetology, Herpetological Review, Facsimile Reprints in Herpetology, Contributions to Herpetology, Herpetological Circulars, Herpetological Conservation*, and the *Catalogue of American Amphibians and Reptiles* (see below for CAAR details). SSAR members receive prepublication discounts on all *Facsimiles* and *Circulars* and on volumes in the *Contributions* and *Herpetological Conservation* series. A complete pricelist of Society publications is available at: http://www.ssarbooks.com/.

CATALOGUE OF AMERICAN AMPHIBIANS AND REPTILES

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available for purchase from the SSAR Bookstore (http://www.ssarbooks.com/). Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1–880	check website below for current pricing
INDEX TO ACCOUNTS 1–400: Cross-referenced, 64 pages	$6
INDEX TO ACCOUNTS 401–600: Cross-referenced, 32 pages	$6
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)	$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)	$35
INCOMPLETE SET: NUMBERS 1–190	$75
191–410	$85
411–840	$320

To order: make checks payable to "SSAR" and mail to Breck Bartholomew, SSAR Publications Secretary, P.O. Box 58517, Salt Lake City, Utah 84158, USA (fax 801/453-0489). e-mail: ssar@herplit.com. Online orders at: http://www.ssarbooks.com/.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

www.ssarherps.org

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology*, and its bulletin, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*.

Southernmost Reports of the Hawksbill Sea Turtle, *Eretmochelys imbricata*, in Temperate Waters of Argentina and Evidence of a Hybrid Origin Supported by Mitochondrial DNA Analysis

The Hawksbill Sea Turtle, *Eretmochelys imbricata* (Linnaeus 1766), is the most tropical of all sea turtle species, distributed along the central region of the Atlantic, Pacific, and Indian oceans (Mortimer and Donnelly 2008; Witzell 1983). The species lives in close association with hard-substrate communities such as coral reefs, foraging primarily on sponges, and may also occur in coastal lagoons and bays (Meylan 1988; Plotkin 2003).

For a long time, hawksbills, in contrast to the other species of sea turtles, were thought to not undertake extensive migrations (Carr et al. 1966; Van Dam and Diez 1998; Witzell 1983). However, satellite tracking and mark-recapture studies have provided information about movements of the species, which are on the scale of hundreds of kilometers (Bellini et al. 2000; Marcovaldi et al. 2012; Parker et al. 2009; Troëng et al. 2005; Van Dam et al. 2008; Whiting and Koch 2006).

The main nesting areas are located between the Tropics of Cancer and Capricorn (Pilcher 1999; Pilcher and Ali 1999; Witzell 1983). In the western Atlantic Ocean, they are found in the southeastern United States, along the entire Central American coast, through the Greater and Lesser Antilles, southward to Brazil (Beggs et al. 2007; Bjorndal et al. 1985; Blumenthal et al. 2009; Lagueux et al. 2003; Lara-Ruiz et al. 2006; Marcovaldi and Chaloupka 2007; Meylan and Redlow 2006; Richardson et al. 2006; Tomás et al. 2010; Troëng et al. 2005; Van Dam et al. 2008; Fig. 1). In the southwestern Atlantic, the nesting and feeding grounds of hawksbills are mainly along the northeastern coast of Brazil, the Atol das Rocas and Fernando de Noronha archipelagos, and the Arvoredo and Abrolhos islands (Marcovaldi and Chaloupka 2007; Marcovaldi et al. 1999; Proietti et al. 2012; Sanches and Bellini 1999; Fig. 1). The southernmost recorded feeding ground is in Mostardas (30.88027°S, 50.60666°W) on the coast of Rio Grande do Sul, Brazil, where a live juvenile was found (Valls et al. 2011).

Genetic analyses of hawksbills based on a short mitochondrial DNA (mtDNA) fragment (384 bp of the control region) were used to characterize several Atlantic nesting areas (Bass 1999; Bass et al. 1996; Bowen and Karl 1996; Bowen et al. 2007; Blumenthal et al. 2009; Browne et al. 2007; Diaz-Fernandez et al. 1999) and some feeding areas in the Caribbean (Bowen et al. 1996; Browne et al. 2007; Tröeng et al. 2005; Fig. 1). Recently, genetic studies based on longer mtDNA sequences (760 bp) in western Atlantic nesting areas identified 47 polymorphic sites that determined a total of 25 haplotypes, improving the ability to detect population structure in hawksbills and suggesting probable hybridization events (Lara-Ruiz et al. 2006; Leroux et al. 2012; Vilaça et al. 2013). Specifically, Caribbean feeding grounds showed the likelihood of transoceanic migrations (Bass et al. 1996; Bowen et al. 2007; Velez-Zuazo et al. 2008). Monzón-Argüello et al. (2010) demonstrated the occurrence of young hawksbills from the Caribbean nesting areas in feeding grounds off Cape Verde, corroborating mark-recapture results (Bellini et al. 2000; Marcovaldi and Filippini 1991).

The Hawksbill Sea Turtle is classified as Critically Endangered by the IUCN (Mortimer and Donnelly 2008). The most serious problem this species encounters is harvest by humans. Hawksbills have largely been exploited for their shells, which are used for decorative purposes (Meylan and Donnelly 1999). Effective conservation relies on accurate knowledge of the population distribution, including characterization of nesting and feeding areas and migration patterns. The analysis of hawksbill turtles in the southwestern Atlantic including southernmost reports in

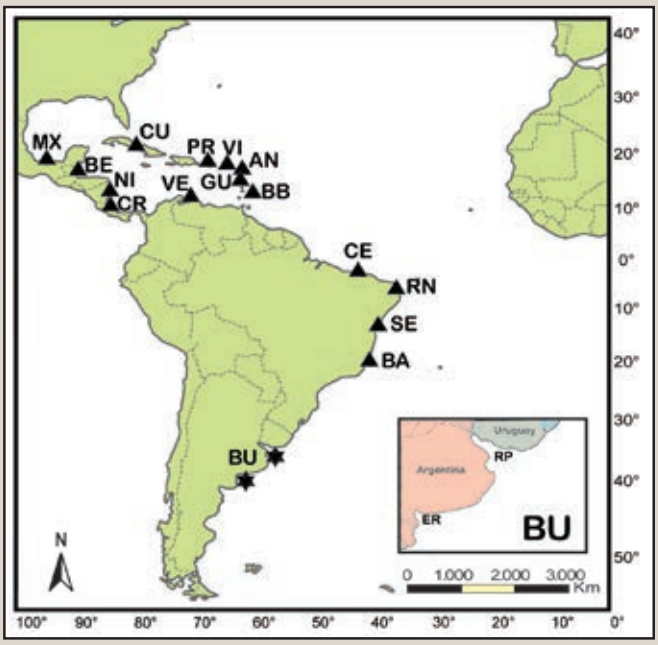

FIG. 1. The map shows the nesting grounds of Hawksbill Sea Turtles throughout the Atlantic Ocean. Individuals collected off the coast of Buenos Aires (BU) in Argentina are symbolized by stars (RP, Rio de la Plata estuary; ER, El Rincon estuary, inset map). References and abbreviations for nesting colonies (indicated by triangles) considered possible sources of turtles found in Argentina are: Cuba (CU), Puerto Rico (PR), Virgin Islands (VI), Antigua (AN), Guadaloupe (GU), Barbados (BB), Venezuela (VE), Costa Rica (CR), Belize (BE), Nicaragua (NI), Mexico (MX) and States of Bahia (BA), Rio Grande do Norte (RN), Sergipe (SE), and Ceara (CE) (Lara Ruiz et al. 2006; Leroux et al. 2012; Vilaça et al. 2013).

FIG. 2. Photo of the Hawksbill Sea Turtle found in San Clemente del Tuyú, Buenos Aires, Argentina.

temperate waters improves our understanding of this aspect of their biology.

In recent years, the Regional Program for Sea Turtle Research and Conservation of Argentina (PRICTMA) has analyzed the presence of sea turtles in the temperate waters of Argentina, identifying life-history stages as well as the genetic diversity and probable origin of individuals (Prosdocimi et al. 2012). Previously, Green (*Chelonia mydas*), Loggerhead (*Caretta caretta*), and Leatherback (*Dermochelys coriacea*) sea turtles have been confirmed in Argentinean feeding grounds (Gonzalez Carman et al. 2011). Here we report analyses of the southernmost records of Hawksbill Sea Turtles in the southwestern Atlantic along the Argentina coast using morphological and mtDNA markers. An extension of the distribution range for this critically-endangered species can reveal novel potential habitats. Such critical information can be combined with knowledge of the species' life cycle in the Southern Hemisphere to further conservation efforts.

Materials and Methods.—Beaches and ports along 2800 km of the maritime and fluvial coast of Argentina were regularly surveyed by PRICTMA from 2009 to 2010. Turtles found were weighed, measured, and sampled for genetic analysis according to Bolten (1999) and Dutton (1996). The specimens for this study were identified as *Eretmochelys imbricata* following morphological keys of Pritchard and Mortimer (1999). To classify individuals in life stages, we considered the criteria of Sanches and Bellini (1999) and Vélez-Zuazo et al. (2008). Turtles below 35 cm curved carapace length (CCL) were considered "small" (juveniles with little swimming capacity and hence subject to being dispersed by oceanic currents), whereas turtles with a CCL 35–65 cm were considered "large" (juveniles that probably have a capacity to swim independent of oceanic currents).

A DNAeasy Tissue Kit was used for DNA extractions, following the manufacturer's instructions for animal tissues (Qiagen, Inc.). A 760 bp mtDNA control region fragment was amplified in both directions using primers LCM15382 (5´-GCT TAA CCC TAA AGC ATT GG-3´) and H950 (5´-GTC TCG GAT TTA GGG GTT TG -3´; Abreu-Grobois et al. 2006). Polymerase chain reaction (PCR; 1.5 mM $MgCL_2$, 1× PCR Buffer, 200 µM each dNTPS, 0.5 µM each primer, 0.6 U Taq from Invitrogen Life Technologies, 1 µl template DNA and H_2O to a total volume of 50 µl) was carried out under the following conditions: 10 min at 95°C, 35 cycles of 1 min at 94°C, 30 cycles of 1 min at 50°C, and 1 min at 72°C, followed by 5 min at 72°C (Shanker et al. 2004), using a MGW Biotech Primus PCR System. The samples were purified and sequenced using the MACROGEN, Inc. (Seoul, South Korea) sequencing service.

Sequences were edited and aligned using the Bioedit V 7.0 (Hall 1999) and Clustal programs (Higgins and Sharp 1988). Polymorphic sites were identified using GENALEX 6 (Peakall and Smouse 2006).

To infer the possible origin of the turtles, we compared our results with data from 13 Caribbean and Brazilian nesting beaches: Cuba (CU), Puerto Rico (PR), Virgin Islands (VI), Antigua (AN), Guadeloupe (GU), Barbados (BB), Venezuela (VE), Costa Rica (CR), Belize (BE), Nicaragua (NI), Mexico (MX), and the Brazilian states of Bahia (BH), Rio Grande do Norte (RN), Sergipe (SE), and Ceara (CE) (Lara Ruiz et al. 2006; Leroux et al. 2012; Vilaça et al. 2013; Fig. 1, Table 1).

Results.—In April 2009, a live turtle was incidentally captured near Bahía Samborombón (36.24405°S; 56.97686°W) in an artisanal coastal gillnet fishery from San Clemente del Tuyú, Rio de la Plata Estuary (RP in Fig. 1 inset map; Fig. 2). In March 2010, a second turtle was found stranded dead on the coast of Monte Hermoso, El Rincon Estuary (38.99005°S; 61.27847°W; ER in Fig. 1 inset map). Morphological studies identified both specimens as large juvenile Hawksbill Sea Turtles, with CCLs of 53.0 cm and 40.8 cm and curved carapace widths of 50.5 cm and 40.3 cm, respectively.

Sequences of 760 bp in the mtDNA control region were successfully amplified from skin samples. Qualitative comparison to published data suggests that the two samples match with the EiBR3 haplotype, which previously had been described only from Brazilian nesting beaches (Table 1).

Discussion.—The present study details the southernmost records of Hawksbill Sea Turtles in the western Atlantic. Results presented here also provide insight into the morphological and genetic characterization of hawksbills at temperate latitudes, while improving knowledge of the distribution of the species. Indeed, genetic analysis based on 760 bp mtDNA sequences revealed that both specimens from Argentina correspond to the haplotype Ei-BR3 that has been detected only in Brazilian rookeries (Vilaça et al. 2013). Our results suggest that Brazilian nesting colonies might be a main contributor of hawksbills along the Argentinean coast.

Population genetic analysis of nesting beaches in the State of Bahia, Brazil, based on the same mtDNA fragment showed that the third most frequent haplotype (42%) was Ei BR3. This haplotype is phylogenetically close to haplotypes described for *C. caretta* (CC A4), suggesting the existence of hybridization in nature (Lara-Ruiz et al. 2006). Studies of several nesting areas in Brazil using nuclear markers support this view and suggest that hybridization is a recent phenomenon, spanning about two generations or 40 years (Vilaça et al. 2012, 2013). Postulated hybridization events at sea turtle nesting beaches in Brazil might be related to overhunting and environmental changes associated with coastal modifications (Vilaça et al. 2012).

Both specimens analyzed here had the morphology of *E. imbricata*, but exhibited a mitochondrial genome similar to that of *C. caretta*. Thus, a loggerhead female × hawksbill male hybridization event would explain the origin of specimens detected in Argentina. The suspected hybrid nature of the turtles phenotypically identified as hawksbills also might explain the occurrence of individuals of a species with a tropical distribution at temperate latitudes. That both specimens were large juveniles with probable capacity to swim independently of oceanic currents suggests that they did not arrive along the Argentine coast by chance. Indeed, satellite telemetry found that female hybrids derived from an *E. imbricata* × *C. caretta* mating could migrate to feeding areas of either progenitor species (Marcovaldi et al. 2012). Our results identify *E. imbricata* × *C. caretta* hybrids along Argentine coasts, a feeding ground of *C. caretta* (Prosdocimi 2012).

The detection of hybrid individuals of hawksbills in the western Atlantic indicates the need for increased sampling effort in geographical regions not yet analyzed to study hybridization in this critically-endangered species. Moreover, genetic studies using uniparental and biparental markers are required to clarify the genetic structure and demographic history of hawksbill populations necessary to delineate effective global conservation strategies.

Acknowledgments.—Access to study animals was kindly facilitated by the Regional Program for Sea Turtle Research and Conservation of Argentina (Acuario de Buenos Aires, Aquamarina- CECIM,

and Reserva Natural de Usos Múltiples Bahía Blanca, Bahía Falsa y Bahía Verde). The wildlife agencies of Buenos Aires province and the National Wildlife Agency of Argentina issued permits and supported our research. We are also grateful to the fishermen from San Clemente del Tuyú, Ingeniero White, Puerto Rosales, and Villa del Mar who provided information and collaborated with the program. Funding was provided by the Buenos Aires Zoo, Fondo para la Conservación Ambiental from Banco Galicia, and Universidad de Buenos Aires (X-00412). We are also grateful to J. H. Otero for his helpful assistance in figure preparation. This study adhered to the legal requirements of the countries in which the work was carried out and to all institutional guidelines.

Limb Malformations of the Critically Endangered Stream-breeding Frog *Isthmohyla rivularis* in the Monteverde Cloud Forest Preserve, Costa Rica

Amphibian limb malformations have been known to science as early as the eighteenth century (Ouellet 2000). Common causes of limb malformations include trematodes (Sutherland 2005), chemical pollutants in the water (Taylor et al. 2005), and predation (Ballengee and Sessions 2008). Limb malformations have been documented primarily in North America and Europe (Ouellet 2000; Pinya et al. 2012), and recently in Africa (Hassine et al. 2011) and South America (Peltzer et al. 2011). Malformations have been noted in a number of amphibian families including the family Hylidae (Johnson and Lunde 2005). However, to our knowledge limb malformations have not been documented as occurring in Central America, nor in the genus *Isthmohyla* (Hylidae). Herein we report the first records of limb malformations of *Isthmohyla rivularis* found in Costa Rica.

Isthmohyla rivularis is a critically endangered, small-sized frog endemic to Costa Rica and Panamá (Stuart 2008). They occur in humid premontane and montane cloud forests at elevations ranging from 1210–2040 m, and are normally found in vegetation alongside fast moving streams (Savage 2002). Although amplexus and egg deposition have not been reported for this species, tadpoles develop in streams and may be encountered in riparian pools (Duellman 2001; Savage 2002). *Isthmohyla rivularis* was formerly a common species, but in the late 1980s they experienced severe declines and were not encountered for nearly 20 years in Costa Rica (IUCN 2012). However, a population was

FIG. 1. Study stream segment and representative habitat of the population of *Isthmohyla rivularis* where limb malformations were detected on the Atlantic slope of the Cordillera Tilarán, Costa Rica.

FIG. 2. Hind limb malformations observed on the frog *Isthmohyla rivularis* representing brachdactyly and syndactyly (A); and brachydactyly and ectromelia of the fibulare, tibiale, and digits (B).

recently discovered in the Monteverde Cloud Forest Preserve (MCFP) and was the source upon which we made our observations.

As part of a larger study investigating the occurrence of the pathogenic fungus *Batrachochytrium dendrobatidis*, we surveyed a stream for *I. rivularis* on the Atlantic slope of the Cordillera Tilarán in the MCFP (10.32°N, 84.77°W, datum WGS84; elev. 1350 m). The stream occurs in primary cloud forest and consists mainly of riffles and glides (69%) with some rapids and cascades (27%) and occasional pools (4%). The 303 m section of stream we surveyed had a mean wetted width of 2.3 m and a mean center depth of 0.2 m. The primary substrate was cobble with some areas of boulders and coarse woody debris (see Fig. 1). Surveys were conducted on 13, 14, and 15 June 2011 between 1815 h and 2130 h. We captured twelve adult *I. rivularis* males; of these, three (25%) were observed to have rear limb malformations of brachydactyly (shortened toes) and syndactyly (fused digits) N = 1, and/or ectromelia of the fibulare, tibiale, and digits (absence of the foot from the ankle down) N = 2 (Meteyer 2000) (see Fig. 2).

Many limb malformations are attributed to limb bud disruption by trematodes of the genus *Ribeiroia* (Johnson and Lunde 2005). However, this seems unlikely in this instance, as we did not encounter intermediate host snails (Planorbidae) during diurnal bank-to-bank belt transect stream surveys (Welsh and Ollivier 1997) aimed at detecting tadpoles. Pinya et al. (2012) suggest *Ribeiroia* as a possible cause of limb malformations they observed in the endangered midwife toad *Alytes muletensis*. However, similarly to Pinya et al. (2012) we were unable to justify sacrificing individuals of a critically endangered species to inspect for metacercarial cysts (Johnson and Paul 2011).

Another possible cause may be trauma as a result of predation attempts. Bowerman et al. (2010) determined that aquatic predators were the probable cause of missing-limb malformations in two different species of frogs in Oregon, USA. In Costa Rica, Warrington and Cossel (2012) described crab predation on the related *Isthmohyla pseudopuma* within the Monteverde

Cloud Forest Preserve. Furthermore, we observed six crabs (*Epibolocera sinuatifrons*) within the stream segment along which the malformed frogs were encountered. However, we presume that malformations caused by crab predation would likely be missing or truncated limbs rather than the apparent developmental abnormalities we observed.

Chemical pollutants are another possible cause of the malformations. Taylor et al. (2005) found the risk of amphibian limb malformations was double when near agricultural land use. Further, only 2% of the malformations they observed were extra limbs, whereas the remaining malformations were either missing (26%) or malformed (72%) limbs (Taylor et al. 2005). The types of malformation we observed were similar to those of Taylor et al. (2005). Chemical pollutants as an etiology are puzzling because our study stream is extremely remote from any point sources of pollution other than an infrequently used cabin operated by the Tropical Science Center. However, LeNoir et al. (1999) reported airborne agricultural pesticide transport in the Sierra Nevada Mountain Range, and the prevailing winds at our study site carry moisture upslope from major agricultural activity along the Atlantic coast. This movement of air and moisture and the concentrating effects of fog and clouds (Hayes et al. 2010) could possibly transport contaminants to our study site and result in deposition at concentrations sufficient to cause limb malformations.

Ultraviolet light has been implicated as a cause of limb malformations in both lab and field settings (Ankley et al. 2000; Pahkala et al. 2001). Malformations caused by UV exposure are often bilaterally symmetric (Ankley et al. 1998). Although not perfectly symmetric, the general type of limb malformations observed on each frog displayed bilateral similarity (see Fig. 2). An assessment of amphibians in northern Wisconsin and Minnesota by Diamond et al. (2002) concluded that the risk of limb malformation caused by UV was low. The ambient levels of UV at our study site are unknown. However, this possible cause should be explored further.

Another possible cause of the limb malformations we observed is congenital defects. The rediscovery of this species after approximately 20 years of not being detected within the reserve may suggest a relictual population and a possible genetic bottleneck. Although there are no studies we are aware of that correlate inbreeding in amphibians with an increased incidence of malformations, observations by Pinya et al. (2012) occurred in populations that had been re-established, and may also represent a scenario where genetic variability was limited.

Our observation of limb malformations in *Isthmohyla rivularis* raises yet another concern for the conservation of this critically endangered frog species. Malformations may reduce recruitment (Hayes et al. 2010) and subsequently have negative impacts on the persistence of small, re-emerging populations. Therefore, understanding the cause of these malformations may be important for future conservation efforts of this critically endangered species.

Acknowledgments.—We thank A. Olsen, J. Warrington, J. Cossel, and R. Cossel of Northwest Nazarene University for their assistance in the field. We are also indebted to the following people of the Tropical Science Center for help in conducting the stream surveys (G. Alvarado, S. Vargas, and O. Vargas), assisting with logistics and permitting (Y. Méndez and C. Mena) and supporting our work in the preserve (C. Hernández and A. Pounds). Funding was provided in part by the Murdock Life Science and Research Grant #2009260. Our work was conducted under Ministerio del Ambiente, Energia y Telecomunicaciones Scientific Passport #04698. Animals were released unharmed after sample collection, photography, and measurements and all authors have complied with the Animal Care guidelines during this research and obtained all necessary state, federal, and international permits.

Quantification of Color Pattern Variation in the Common Gartersnake (*Thamnophis sirtalis*) from Two Coastal Islands and Mainland, Massachusetts, USA

The Common Gartersnake (*Thamnophis sirtalis*) inhabits a wide variety of ecosystems and has been extensively studied throughout most of North America (Gregory and Larsen 1993; Rossman et al. 1996). Conspecific variation in both morphology (Grudzien et al. 1992; King 1988) and color patterns (Kelley et al. 1997; Mooi et al. 2011) have been documented within and between populations of several *Thamnophis* species (Brodie 1989; Ruthven 1908; Westphal and Morgan 2010). In general, color pattern variation in snakes is presumed to reduce predation risk through interacting mechanisms normally including background matching and color pattern-specific antipredator behaviors (Brodie 1992), mimicry (Brodie 1993), or aposematic coloration (Williams et al. 2004), but it has also been linked to thermoregulatory efficiency (Bittner et al. 2002; King 1988).

Although color patterns are not a definitive method to determine species, subspecies, or distinct genetic lineages, variable patterns are important to consider because differential selective pressures can exist in each population (Brodie 1992). *Thamnophis sirtalis* exhibits population-specific phenotypes without necessarily being genetically distinct (Gregory and Larsen 1996; King 2003; King and Lawson 2001; Mooi et al. 2011; Westphal 2007; Westphal and Morgan 2010). In spite of considerable research on various *T. sirtalis* subspecies from central and western North America and the Maritime Gartersnake (*T. s. pallidulus*) from Nova Scotia, Canada (Allen 1899; Barnes et al. 2006; Bleakney 1959; Gilhen 1984, 2010; Rye 2000), there have been very few quantitative measurements of color patterns comparing populations or subspecies of the Common Gartersnake in the northeastern USA.

Our objectives were 1) to develop a standardized method for measuring color pattern variability, and 2) to compare color patterns between *T. sirtalis* populations from two islands and mainland Massachusetts. To achieve our first objective, we used a pattern analysis similar to that developed by Westphal (2007); however, we based our analysis on macrodigital images of partially stretched skin and scales on two specific regions of live *T. sirtalis*. We then quantified the area of lateral blotches (black) relative to scales and dorsal stripe completeness of *T. sirtalis* from Nantucket and mainland Massachusetts.

Study Sites and Methods.—We used high-resolution digital macro-photography to examine patterns of pigment on scales and skin of adult *T. sirtalis* from the islands of Nantucket and Tuckernuck and the mainland of Massachusetts. Nantucket Island is 118 km^2 and is the largest of three islands within Nantucket County, Massachusetts. Tuckernuck Island is 3.6 km^2 and approximately 1 km W of Nantucket. These islands are approximately 40 km S of the closest mainland (Cape Cod) and 15 km E of the nearest large island, Martha's Vineyard, Massachusetts.

We analyzed scales for stripe and blotch on 32 Nantucket snakes, 28 Tuckernuck snakes, and 26 specimens from four counties on the mainland of Massachusetts (Middlesex [N = 5], Worcester [N = 16], Hampshire [N = 1], and Hampden [N = 4] counties) between 2008 and 2011 (Fig. 1). All snakes had a body mass of greater than 10 g and a snout–vent length (SVL) greater than 250 mm and were released after being photographed. One person could obtain digital images for analysis in the field by using the following procedure. Snakes were gently pressed against a firm surface, usually the photographer's upper leg, while kneeling on the opposite leg to provide stability for the camera and specimen. While holding the snake, the photographer gently stretched the skin and scales to expose the lateral blotches on the left side of the snake approximately one-fourth the SVL as measured from the snout. Instead of pressing the snake too firmly, holding the snake and watching the expansion and contraction of the skin during breathing provided a passive method of obtaining the best image. When a snake inhales, the anterior portion of the body expands and the skin is exposed between the scales to provide a good image of the lateral skin pattern. After a snake was in position, it relaxed and began breathing rhythmically and we timed the photograph with the breathing. The snake was then slightly rolled on to its ventral scales so that a second set of photographs could be taken of the dorsal stripe in the same region of the snake's body.

Our analysis of the dorsal stripe focused on the amount of black pigment on the scales where we counted seven scales along the dorsal stripe, normally row 10, and estimated the amount of black pigment on each scale (Fig. 2). No black on the scale was scored zero; black on 1–25% of the scale was scored 0.25; 26–50% was scored as 0.5; 51–75% was 0.75; and 76–100% was scored

as 1.0. The total score was summed to provide a stripe score for each snake (range from 0–7). We developed a scoring system for analysis of lateral blotches using the same concepts described by Westphal (2007). We analyzed an area defined by five rows of scales dorsal to the lateral stripe (scale rows 4–8) and seven scales anterior to the site of reference. For each of the 35 scales in this area, we estimated the percent of the scale's border adjacent to dark interscalar skin that formed a dark, pigmented blotch (Fig. 2). If there was no dark pigment on the interscalar skin adjacent to the scale, the score was zero. Any dark pigment on the interscalar skin from approximately 1–25% of the scale's border resulted in a score of 0.25, 26-50% of the scale bordering black pigment was 0.5, 51–75% was 0.75, and 76–100% was 1.0. The total score for each row was summed then divided by five (number of rows scored) to provide an average blotch-per-row score for each snake. In many instances more than one image had to be reviewed, often from the dorsal image, to see around the curve of the snake for rows 7–8.

We used Minitab 12.1 (1999 Minitab, Inc., State College, Pennsylvania) to test the data for normality, examine basic statistics, and compare the two response variables, lateral blotches and dorsal stripe between mainland snakes (pooled all samples) to the island specimens (pooled per island) using ANOVA General Linear Model and Tukey pairwise comparisons. To confirm that the variation in color pattern was not a sexually dimorphic trait, we used a *t*-test to compare stripe and blotch scores between all males and females, and there was no significant difference (Blotch, $P = 0.23$, Stripe, $P = 0.70$). Therefore, we pooled males and females in the color pattern analysis. We used ANOVA General Linear Model to compare mainland and island population data sets. The blotch and stripe data were normally distributed and comparisons were tested at $\alpha = 0.05$.

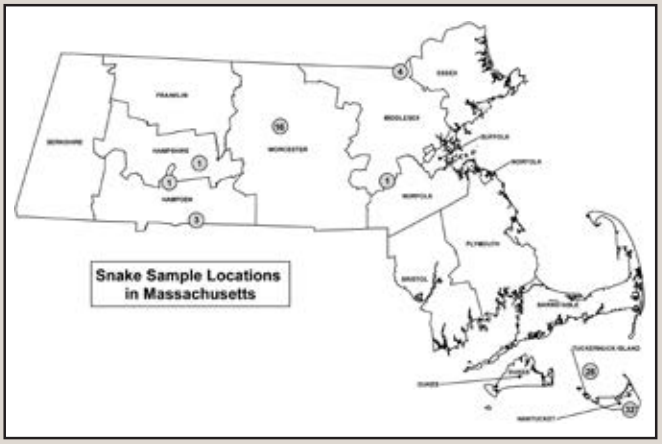

Fig. 1. Approximate location and number of *Thamnophis sirtalis* photographed for color pattern analysis.

Fig. 2. Examples of scores for each scale for the dorsal stripe and black blotches from one mainland snake (A. and B, Holyoke, Hampden Co.) and one island snake (C. and D.,Nantucket, Nantucket Co.).

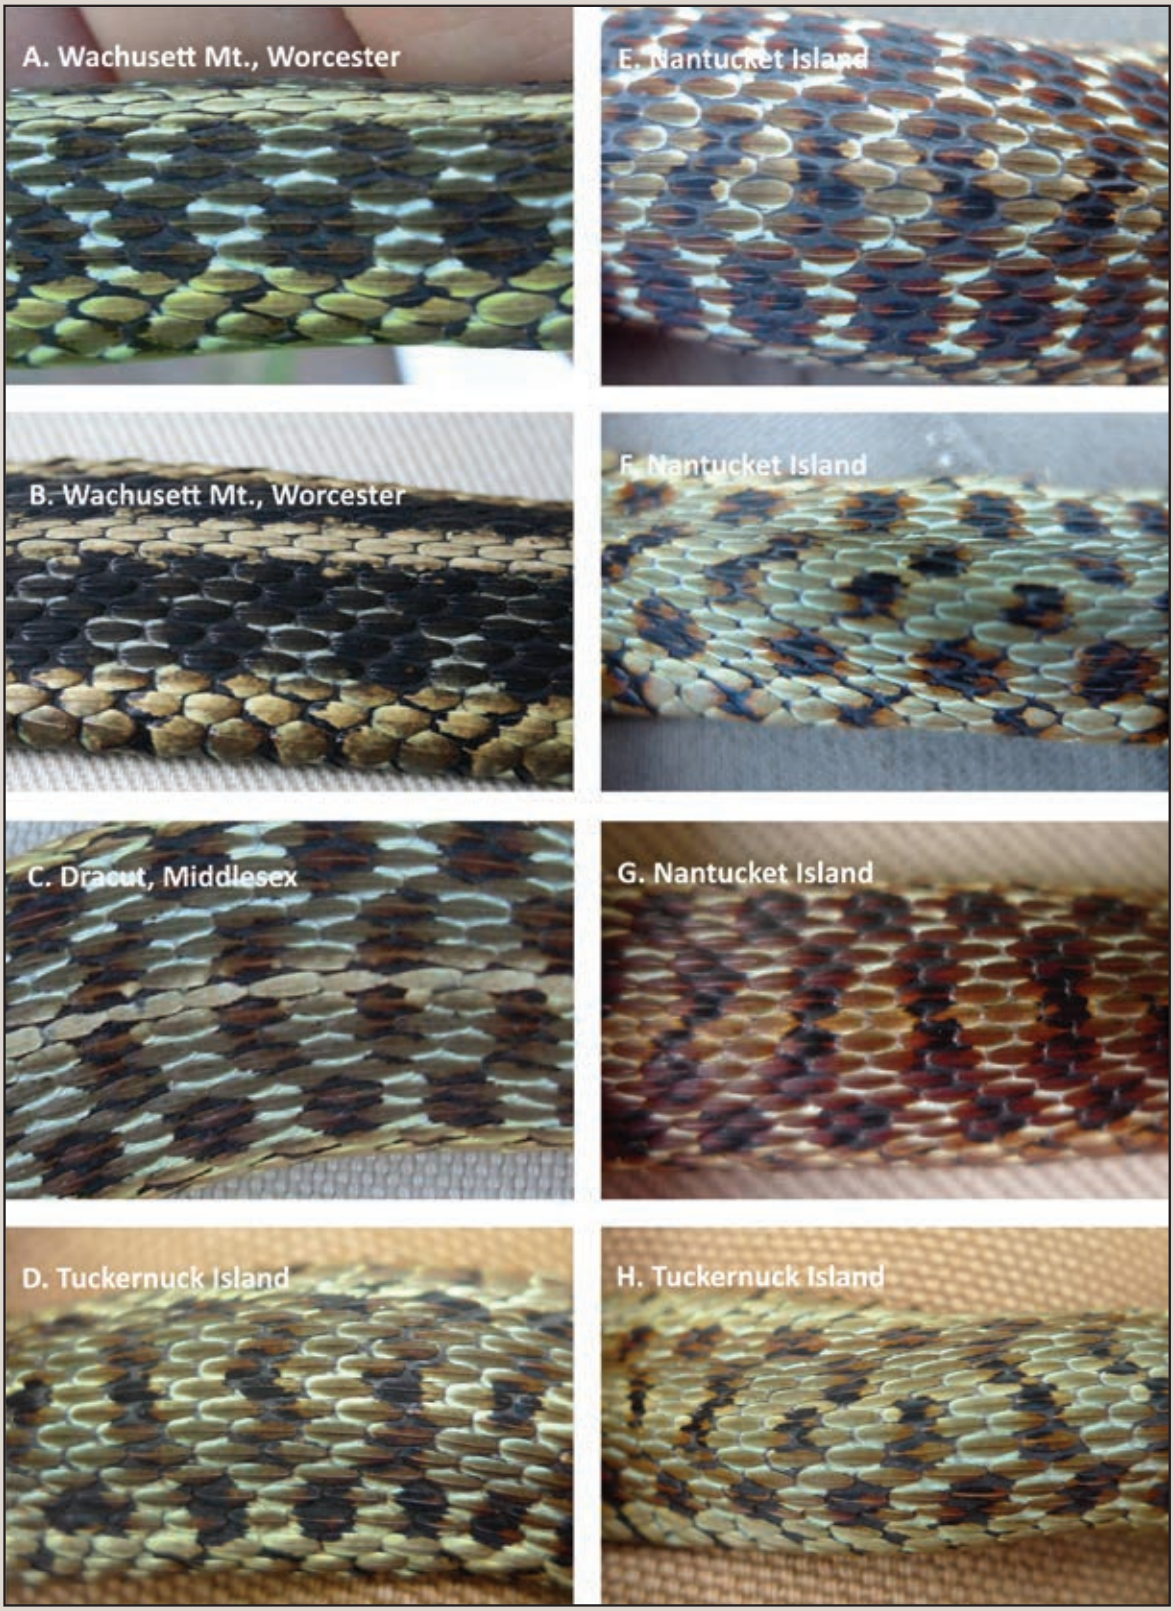

FIG. 3. Representative photographs of patterns of snakes from non-coastal counties and from the islands of Nantucket and Tuckernuck, Massachusetts. The specimens in A-C are from the mainland (A. and B., Wachusett Mountain, Princeton, Worcester Co.; C. Dracut, Middlesex Co.) while those in D-G are from the islands (D. and H. Tuckernuck Island, Nantucket Co.; E-G Nantucket Island, Nantucket, Co.).

Results and Discussion.—There was significantly less dark pigment within the dorsal stripes of mainland snakes (N = 26, 0.63 ± 0.13 (mean ± 1 Standard Error [SE]) compared to snakes from Nantucket (N = 32, mean = 2.20, ± 0.12) and Tuckernuck islands (N = 28, mean = 2.09, ± 0.10, $F_{2, 85} = 58.9$, $P < 0.001$). The stripe scores from Tuckernuck and Nantucket were not significantly different ($P = 0.74$). Lateral blotches on snakes from Nantucket (N = 30, mean = 3.53 ± 0.09) were significantly smaller than snakes from the mainland (N = 25, mean = 4.23 ± 0.083, P <0.001), and Tuckernuck (N = 28, mean = 4.06 ± 0.14, $F_{2, 82} = 11.7$, $P = 0.002$). However, lateral blotches on snakes from Tuckernuck did not differ from those on mainland snakes ($P = 0.532$).

Our results indicate that *T. sirtalis* from two coastal islands have significantly more black pigment on the dorsal stripe compared to snakes from the Massachusetts mainland. The snakes from Nantucket and Tuckernuck had discontinuous stripes with dorsal blotches that were sometimes fused with lateral blotches to form dark cross bands. There was no significant difference between lateral blotch areas of snakes from the mainland compared to Tuckernuck, but snakes from Nantucket had significantly less blotch area than mainland snakes.

There are several possible explanations for the significant differences resulting from our color pattern analysis. The spotted pattern on island snakes may be related to antipredator behaviors, thermoregulation, or genetic drift. A snake's likelihood of fleeing potential visual predators has been linked to color patterns (Brodie 1992; Jackson et al. 1976), and the contrasting pattern exposed when a *T. sirtalis* flattens its body to reveal rows of dark blotches or pigment on the skin between the scales may elicit a startle response from visual predators. Indeed, others have shown that within *Thamnophis ordinoides*, striped individuals are more likely to flee predators compared to spotted individuals which are more likely to remain motionless and rely on crypsis to avoid predation (Brodie 1989). Unlike their mainland counterparts, *Thamnophis sirtalis* from the islands of Nantucket and Tuckernuck are not exposed to mammals that potentially prey upon snakes, though feral cats (*Felis domestica*) are an introduced predator that may or may not be ecologically important in some areas (Massachusetts Department of Fish and Game, 2011). Additional studies investigating antipredatory behaviors could assist in determining the relative importance of predation in maintaining such color pattern variation in *T. sirtalis* on these islands and the adjacent mainland.

Thermoregulation is another possible explanation for differences in lateral blotches between Nantucket and mainland snakes. A study on differences in thermoregulation of melanistic gartersnakes demonstrated that the larger area of black pigment is functionally beneficial to adult snakes and likely most important to gravid females (Bittner et al. 2002). Finally, the varying color patterns may be due to genetic drift, and the varying color patterns are the result of relatively small founding populations, thus have no selective advantage.

Lazell (1976) inferred that color variation of *T. sirtalis* from the coastal islands and Cape Cod Massachusetts may be relict populations of *T. sirtalis pallidulus*, suggesting a postglacial dispersal-driven hypothesis: cold-tolerant snakes advanced north with the glacial retreat and were stranded on the islands as sea level increased and cut off any overland dispersal vectors. Bleakney (1959) provided a detailed review of *T. s. pallidulus* including descriptions of color patterns, scale formulas, and hybrid zones from the northeastern USA and adjacent Canada. Rye (2000) reported a genetically distinct maritime lineage of *T. sirtalis pallidulus* in northeastern Maine and the Maritime provinces of Canada, providing validity to the historic range map of the subspecies by Bleakney (1959). This subspecies has been most thoroughly studied in Nova Scotia, Canada, where morphological variation, life-history, and general ecology have been documented (Gilhen 1984). Populations on smaller islands of Nova Scotia have also exhibited variation in color patterns (Barnes et al. 2006).

Methods used in this study are likely to be useful range-wide for *T. sirtalis* as well as other species. Additional studies of patterns of *T. sirtalis* from other nearby islands and populations along the coast and inland could reveal different patterns than those reported herein. This may provide insight into how population-specific selective pressures influence isolated populations of *T. sirtalis.* Our methods could be used to compare color patterns of *T. sirtalis* and *T. s. pallidulus* from the maritime provinces of Canada or northern New England to determine if historically recognized subspecies are functionally different.

Collecting data from live snakes is advantageous because the elasticity of the skin allows close examination of true color patterns, which is often difficult or impossible when examining preserved specimens. Although the snakes often bite and struggle to escape, by restricting data collection to photographs of a relatively small region of the body, we reduce the specimen's discomfort and overall resistance allowing for a relatively consistent image. We intend to continue studying this species' predisposition to color pattern variability, both on the individual and population level. Future research may lead to a better understanding of how this wide-ranging species not only persists and disperses, but how it is successful throughout variable regions of North America including island habitats.

Acknowledgments.—This study was conducted under Scientific Collecting Permits (#087.08, 087.09, 087.10, 087.11 SCRA) from the Massachusetts Division of Fish & Wildlife. We thank The Nantucket Biodiversity Initiative and Oxbow Associates, Inc. for providing funding. We are grateful for permission to conduct field work by Nantucket Conservation Foundation, Tuckernuck Land Trust, The Trustees of Reservations, Linda Loring Nature Foundation, Wachusett Mountain State Reservation, and many other generous land owners. We are grateful to many field assistants: S. Alger, J. Blyth, R. Carr, R. S. Egan, A. Feldman, A. Heighton, R. Kennedy, R. Kessler, D. Lang, E. LoPresti, C. Mirbach, J. Pelletier, and T. Westlake. We are thankful to L. Perotti of Roger Williams Zoo, for providing field training for field assistants. A. Richmond from University of Massachusetts at Amherst Natural History Collections, as well as J. Martinez and J. Rosado of the Museum of Comparative Zoology provided access to preserved specimens and encouragement to pursue the research. J. Martinez, J. Losos, and R. Clancy provided constructive comments on this manuscript. T. Tada and R. Strohsahl assisted with preparation of figures.

Attaching Radio-Transmitters to Geckos: Trials and Tribulations

Radio-telemetry is considered an important and successful technique for investigating the behavioral ecology of animals under natural field conditions, and for conservation monitoring (Goodman et al. 2009; Warner et al. 2006). The technique relies on attaching radio-transmitters to animals and tracking their location over a period of time in order to study their movement, habitat-use and other behaviours. Several techniques have been employed for attaching transmitters to lizards, including surgical implants (Guarino 2002; Klingerböck et al. 2000; Smith et al. 2010), contact adhesion directly to skin (Mathies and Martin 2008; Sabo 2003), tail mounts (Barr 2009; Germano 2007), collars (Pérez-Buitrago and Sabat 2007) and external harnesses (Flesch et al. 2009; Goodman et al. 2009). Backpack harnesses have shown to be one of the more successful techniques, and have been used effectively on a variety of lizard taxa, including agamids (Doody et al. 2009; Reaney and Whiting 2003; Warner et al. 2006), phrynosomatids (Burrow et al. 2001; Fisher and Muth 1995; Grant and Alberts 2001; Richmond 1998), skinks (Price-Rees and Shine 2011), anoles (Nicholson and Richards 2011), varanids (Guarino 2002; Traholt 1995), and iguanas (Goodman et al. 2009), as well as on tuatara (Ussher 1999). The majority of these groups represent primarily terrestrial lizards (with the exception of *Anolis*) and consequently, backpack designs have focused on utilized materials that are resistent to the force of contact with ground surfaces and wear on harness materials during locomotion (Ussher 1999). The typical heavy keratinized scalation of these groups offers protection against any rubbing or abrasive forces potentially caused by external transmitter harnesses (Goodman et al. 2009).

Geckkonidae on the other hand, differ markedly from other lizard groups in both morphological and behavioral traits. They typically have soft, loose skin with granular scales that do not overlap, and many species are small and arboreal. These characteristics limit the use of standard attachment methods previously mentioned. For example, the small size of most geckos precludes the use of implanted transmitters and their softer skin is likely to be more susceptible to the effects of abrasion by some external attachment methods. Furthermore, the risk of entanglement in foliage and lodgement in crevices is higher in geckos, which tend to seek refuge in tight cracks and fissures. Few published studies have provided details on the methods of attaching radio transmitters to geckos, and fewer still have discussed the successes and/or failures of their techniques (Hare et al 2007; Hoare et al. 2007; Knox and Monks 2013).

New Zealand supports a rich diversity of geckos, with approximately 40 species and undescribed taxa (Hitchmough et al. 2013; Neilson et al. 2011). For the majority of these species, little is known of their natural history due to their cryptic nature, rarity, and often low population densities (Bell 2009). Several studies have trialed radio-telemetry techniques to investigate the behavioral characteristics of some gecko species (Hare et al. 2007; Salmon 2002; Schenyer 2001). Salmon (2002) trialed three different methods for attaching transmitters to geckos, including surgical implants, direct attachment to the dorsal surface with cyanoacrylic glue (Supa Glue®), and a backpack-harness style method. The study recorded poor success with both direct attachment and surgical implants, with transmitters detaching within 24 h and a 50% (4 of 8) mortality of animals following transmitter removal surgery, respectively. Since then most studies have adopted the backpack harness method, trialling a variety of materials and harness designs, and reporting large variations in the longevity of attachment (Table 1). Little value however, has been placed on discussing the beneficial and/or adverse effects of these designs. The lack of published data has hindered progress towards developing effective transmitter attachment methods for geckos.

As part of a wider study aimed at reporting the post-release movements of 39 Duvaucel's Geckos (*Hoplodactylus duvaucelii*) translocated to two protected offshore islands, Tiritiri Matangi Island and Motuora Island, in the Hauraki Gulf, New Zealand, we investigated the effectiveness of radio-transmitter attachment on this species, and discuss our results in the context of previous radio-telemetry studies undertaken on geckos worldwide.

Methods

Radio-transmitter attachment.—Hoplodactylus duvaucelii is a large (up to 320 mm total length, 160 mm SVL, and weight 118 g), nocturnal, terrestrial-arboreal species (Whitaker 1968). They have a propensity to seek small crevices as retreat sites during the day (e.g., holes tree branches and trunks, cracks between boulders, beneath bark, and in sea bird burrows) and emerge at night to forage on the ground, on trees, and in the foliage of

vegetation. The small single-stage radio-transmitters used in this study measured 20 mm x 10 mm with a 150-mm whip antenna (Sirtrack Ltd, New Zealand) and weight of ca. 1.4 g. The battery life of the transmitters was approximately 80 days.

Transmitters were attached to geckos using a backpack harness design, modified from Fisher and Muth (1995), Richmond (1998), and Warner et al. (2006). The material used to form the harness was selected based on perceived comfort, flexibility, and durability in the environment. Two different materials were trialled, including thin (ca. 1 mm thick) black rubber (bicycle inner tubing) and a more flexible material, Co-Flex® (Andover Healthcare Inc.). Co-Flex® is a stretchable, lightweight material with self-adhering and water resistant qualities. Harnesses were cut from the materials using a cardboard template. The harness consisted of two shoulder straps (5 mm wide x 100 mm long) branching from a central pad (25 x 20 mm) (Fig. 1a). The length of the straps allowed enough material to easily adjust the harness to the size of the lizard. A transmitter was glued to the central pad using cyanoacrylate glue (Superglue ™). The harness was placed across the individual's shoulders with shoulder straps pointing anterior along each side of the head. The straps were wrapped over the shoulders, across the chest in an 'X' pattern (Fig. 1c), and then back up behind the opposite foreleg. The ends were subsequently attached to the dorsal surface of the transmitter with a small amount of cyanoacrylate glue (Superglue ™) and any excess strap material was cut off (Fig. 1b). It was expected that the glue would form a weak link in the harness over time, as exposure to the environment caused the glue to become brittle and crack, allowing the animal to climb free of the harness. A small amount of glue was also placed between the straps, at the point where they crossed the chest, to reduce the independent movement of each strap (Fig. 1c). Care was taken to avoid glue coming in contact with the individual's skin and the procedure was performed in open air to avoid excessive inhalation of vapors that could be harmful to the animals. When attaching the Co-Flex® harnesses to the geckos, two additional shoulder straps (4 mm wide) were applied diagonally over the top of the transmitter and crossing the chest to add further rigidity, in accordance with Hoare (2007) (Fig. 1d). The backpack harnesses were fitted neatly but did not constrict the chest and interfere with breathing (Fig. 2). The complete harness including transmitter weighed approximately 3.5 g and accounted for less than 5% of *H. duvaucelii* body weight. Because the weight of an individual lizard can fluctuate over 5% within a normal seasonal cycle (Telford 1970), backpack harnesses used in this study were considered an acceptable weight.

Transmitters were attached to 20 adult *H. duvaucelii* (10 geckos per island) and captive trials, up to one week prior to release, were undertaken to confirm that the geckos were able to undertake natural behaviors and move freely while wearing backpack harnesses.

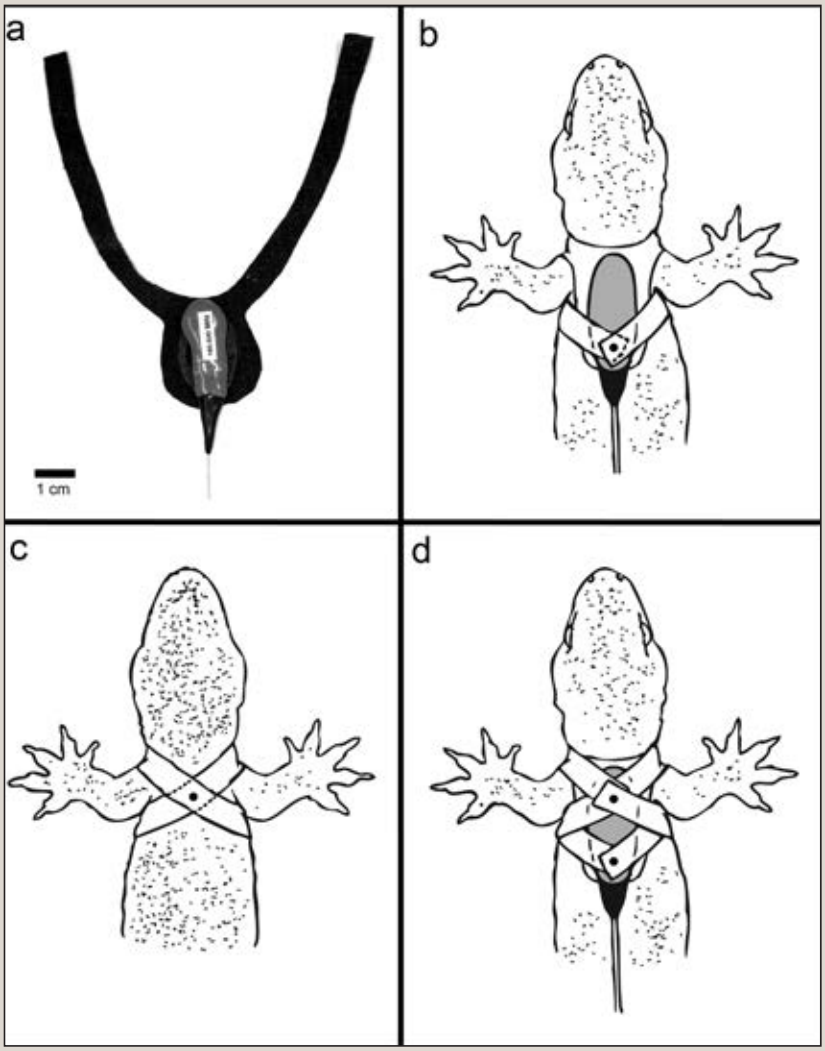

FIG. 1. Attaching a backpack harness to a gecko, a) Co-Flex® harness template with transmitter glued to central pad; b–d) consecutive stages of attachment. See text for details. Black dots (•) indicate where glue was applied to secure straps.

Radio-tracking.—Following the release of the geckos, telemetry signals were received using a hand-held R-1000 telemetry receiver (Communication Specialists Inc.) and a 3-Element Yagi aerial tuned to 160MHz operating frequency (Sirtrack, Havelock North, New Zealand). Transmitters were replaced as their batteries approached the end of their life (i.e. ca. 60 days or within 20% of their battery life) and new transmitters were attached to re-captured animals.

RESULTS

Backpack harness performance.—Backpack harnesses proved a successful method for monitoring the movements and habitat use of *Hoplodactylus duvaucelii* in the present study. On average, the rubber harnesses remained attached for significantly longer periods of time (43 ± 1.6 days; N = 20) compared to Co-Flex® harnesses (12.4 ± 2.4 days; N = 30) ($t = 10.65$, $df = 46$, $p < 0.001$). Body condition indices (weight: SVL ratio), movement, and habitat-use of translocated *H. duvaucelii* did not appear to be negatively affected by radio-transmitter attachment (van Winkel 2008). All geckos carrying transmitters gained body condition and were frequently observed climbing, sprinting at speed, and squeezing through tight vegetation to evade capture. No entanglements in vegetation were recorded. Both harness designs withstood rainfall events, variations in temperatures (12–28°C), and varying degrees of abrasion from rough tree-bark, soil, and rock surfaces.

FIG. 2. Radio transmitter attached to *Hoplodactylus duvaucelii* via a backpack harness, constructed from the flexible Co-Flex® material.

Later in the study, evidence of abrasion became apparent and prompted an immediate abandonment of the rubber material, with all harnesses being replaced with the flexible Co-Flex® material. Injures were recorded in 20% of the geckos wearing rubber harnesses after approximately three weeks of attachment. The injuries were apparent under the armpits and across the dorsal surface of the neckline in areas the rubber material came into contact with the head and moving limbs of the geckos. The injuries ranged from minor abrasions to the skin, resulting in damage or removal of scales, to open lesions in two instances. On one occasion, a small twig (10 mm long) had to be removed from the area between the rubber harness and the gecko's skin. The twig had caused abrasions to the skin after becoming lodged in this space while the gecko was pushing through branches and foliage. The backpacks of wounded individuals were removed immediately and not replaced. Open skin lesions were treated with Betadine® ointment and the rate of healing monitored via opportunistic recaptures of wounded individuals. Monitoring of wounds indicated that lesions took up to three months to heal adequately. In contrast, no injuries were recorded in animals wearing the Co-Flex® harness design. At the completion of the study all transmitters, with the exception of one (due to battery failure), were recovered successfully.

Discussion

Our study verified that the backpack harness design for attaching radio-transmitters to geckos is a convenient and successful technique, provided that consideration is given to selecting an appropriate material for construction of the harness. Backpack harnesses did not appear to constrict or constrain geckos in the present study, with individuals exhibiting natural behaviors typical of the species and showing signs of successful foraging, as indicated by increases in body condition indices. Altered natural behavior and irritation caused by backpack harnesses has been alluded to in previous studies on geckos, immediately following harness attachment (DOC, unpubl. data; Hare et al. 2007; McClure 2011). In most instances the animals soon adjusted to the harness and resumed natural behaviors within periods ranging from 10 minutes (C. Knox, pers. comm.) to a few days (DOC, unpubl. data). Loosening and readjusting harnesses also helped remedy unnatural movements and behaviors in some geckos (C. Knox, pers. comm.).

There were considerable variations in the length of attachment time depending on the type of material used to construct the harness, with rubber harnesses remaining attached to geckos for more than three times as long as the Co-Flex® harnesses. The Co-Flex® material appeared more susceptible to the effects of long-term exposure to environmental conditions than the rubber material, and over time the Co-Flex® lost its elasticity and showed some degree of wear (e.g. fraying and small tears in the material). The difference in durability between the two materials, in relation to the behavioral habits of *H. duvaucelii* (propensity to seek small, tight crevices as retreat sites and move over rough surfaces while foraging) would have contributed to the reduced length of attachment in the Co-Flex® harness. As the material lost elasticity the geckos were able to maneuver out of the harnesses. In comparison, rubber harnesses appeared less susceptible to wear and tear and did not lose flexibility. However, the perceived effects of rubber material on the geckos' skin were severely overlooked as injury was recorded in 20% of the study animals. Considering that injuries were not observed during the short-term captive trials, it is likely that the long-term effect of the rubber material chaffing the soft skin was sufficient to cause abrasion and damage to the skin of the geckos. Furthermore, no evidence was found to suggest that the glue had become brittle allowing the harnesses to detach freely. For these reasons, it is recommended that the rubber material (rubber inner tube) should not be used in future radio-telemetry studies on geckos.

The Co-Flex® material, though more frequently shed by geckos, did not have any detrimental effects on the geckos' skin in the current study. Previous radio-telemetry studies on geckos which used similar cohesive bandage materials have shown that geckos can be tracked for up to two weeks without reported injuries (McClure 2011). However, accuracy and longevity of attachment are likely to be contributing factors to causes of injury. For example, Gerner (2008) reported dorsal skin abrasions and the death of one juvenile *P. guentheri* during a radio-tracking study using a material almost identical to Co-Flex®. However some individuals in the Gerner (2008) study were tracked for up to 58 days, and it is likely that the prolonged effect of movement of the material on the skin may have lead to the adverse effects described. The risks associated with entanglement in vegetation, as well as collection of dirt and debris between the skin and the harness, potentially leading to discomfort and injury also increases with the prolonged attachment time. Gerner (2008) recommended attaching a lightweight padding material under the harness to provide protection against continual movement and rubbing of the harness would be beneficial. Alternative methods to prevent the movement of the harness and transmitter have been trialed by several authors (DOC, unpubl. data; Hoare et al 2007; Knox and Monks 2013; Schneyer 2001; Salmon 2002) using medical adhesive tape or wound closure strips (Table 1). These materials secure the backpack harness to the skin with a light adhesive, reducing damage to the skin and allowing successful harness attachment for up to four weeks in some studies (Schneyer 2001). However it has been suggested that adhesion to scales may interfere with the sloughing process (Schneyer 2001) and Salmon (2002) reported minor scale loss in a study on captive *Naultinus gemmeus*. Light adhesion to the skin would also appear to limit the ability of geckos to maneuver out of harnesses (DOC, unpubl. data; Knox and Monks 2013). However, medical tapes are particularly susceptible to weathering and the glue loses its adhesive qualities over time in the environment, especially if it comes in contact with rainwater (C. Knox, pers. comm.). Adhesive tapes may therefore have limitations where studies are required over longer periods in natural field conditions, and especially in moist environments. Remedying this may rely on close observation to check the integrity of the backpacks and replace the adhesive harnesses as required. An alternative material for attaching backpack harnesses has been trialed on anoles, a group of arboreal lizards with similar behavioral traits and skin morphology to geckos. Nicholson and Richards (2011) used 0.25-in. elastic (Stretch-Rite brand, Rhode Island Textile Company, Pawtucket, Rhode Island 02862) to construct small harnesses. They reported successful results with no interference or disturbance to behavior and no descriptions of injury or other adverse effects.

Understanding the physical and behavioral habits of a gecko, and any limitations caused by environment, is crucial when considering the material and design of a transmitter harness. Our study clearly overlooked the former when selecting the rubber material, leading to high incidences of injury, and as a result this material should not be used in future radio-telemetry studies on

geckos. It is recommended that future studies focus on selecting materials with soft, elastic, and light adhesion qualities to construct backpack harnesses, and that the study period be limited to three to four weeks with regular observations of the individual and harness attachment, to significantly reduce the risk of unwanted injuries. In addition, publishing developments in harness design and reporting both positive and negative results will ensure adaptive development towards a successful and effective method of the highest welfare standards.

Acknowledgments.—We thank Marleen Baling and Manuela Barry for their assistance in attaching transmitters, and Rob Chappell, Carey Knox, Jo Monks, and Mandy Tocher for their comments on telemetry methods. This study was approved by the Massey University Animal Ethics Committee (Protocol 06/98) and the Department of Conservation (permit AK-19734-FAU). Using Decoys to Estimate Detection Probability for Anuran Amphibians During Visual Encounter Surveys

Understanding spatial and temporal patterns in distribution and abundance is a common goal in amphibian ecology, especially in light of widespread population declines (Schmidt and Pellet 2010). Most studies rely on count data, but often do not account for differences in detection probabilities, which can be highly variable among sites and years (Schmidt 2004; Schmidt and Pellet 2010). If documenting the occurrence of a species is the goal of a survey, repeated visits to a locale can be used to minimize the probability of failing to detect a species that is actually present (Williams and Berkson 2004). The cumulative probability of failing to detect at least one individual of a species declines geometrically with repeated visits, and often approaches a value of zero, or perfect detectability, after several visits (Mackenzie et al. 2002; MacKenzie et al. 2003; Williams and Berkson 2004).

Correction for detectability is more complex when the goal is to determine amphibian abundance, and even the term "detection probability" has a different meaning in this context. When determining occupancy, detection probability is defined as the probability of detecting at least one individual, and therefore increases with abundance (Mackenzie et al. 2002; MacKenzie et al. 2003). When determining abundance, detection probability is the probability that a member of the population is included in the count, and can be considered independent of abundance (MacKenzie and Kendall 2002; Nichols et al. 1998; Williams and Berkson 2004). Because true abundance can rarely be known, counts of individuals corrected for search effort are commonly used (Schmidt and Pellet 2010). Catch-per-unit-effort (CPUE) can be used as an index of abundance if the probability of detecting individuals does not differ among surveys, but this is rarely the case (MacKenzie and Kendall 2002). Detection probability varies with weather, season, time of day, habitat structure and observer, thereby making it unlikely that animals are ever equally detectable at different sites or on different visits to the same site (MacKenzie and Kendall 2002). CPUE can be corrected to account for variation in detection (eg. CPUE/detection probability).

Some researchers have conducted experiments to determine detection probability to create an appropriate correction factor for results of field surveys. To determine detection probability of Red-backed Salamanders (*Plethodon cinereus*), Williams and Berskon (2004) repeatedly searched enclosures containing a known number of individuals. As an alternative to using live animals, Dong Saul (2008) used turkey decoys to determine detection probability of Rio Grande Wild Turkeys (*Meleagris galloparvo intermedia*) for aerial and truck-based surveys in three different vegetation communities. We present a similar technique that uses decoys for estimating the probability of detecting individual frogs during time-constrained visual surveys. Our focal species was the Wood Frog (*Lithobates sylvaticus*), specifically recently metamorphosed young-of-the-year (YOY). We tested for differences in detection probability between two types of wetland habitat, pond shorelines and beaver canals, in Miquelon Lake Provincial Park, in the dry mixed-wood boreal forest of Alberta, Canada (Natural Regions Committee 2006). Survey ponds were pothole wetlands between 0.22 and 2.28 ha in area, with shorelines fringed by emergent vegetation (*Typha latifolia*, and *Carex* spp.) surrounded by riparian meadows of grasses and forbs with scattered willows (*Salix* spp.).

We constructed decoys using biodegradable dough: water, white flour, salt, and cream of tartar with cocoa powder to achieve a pale brown color. Decoys were approximately 2.5 cm long (the size of YOY Wood Frogs at our study sites), with shallow ridges running along the body. Three small, dark blue beads were glued around the "head" region to simulate eyes, thus at least one eye was visible regardless of the orientation of the decoy. Half of a wooden toothpick (~15 mm) was inserted into the hind end of the decoy to mimic a leg (Figs. 1 and 2). All decoys were baked in an oven at 90°C for 3 h to dry the dough and improve durability. Approximately 400 decoys were constructed requiring 4 person-hours, with a cost of approximately US $15 for materials.

We deployed 15 decoys haphazardly along each 3 m-wide and 15 m-long transect, which simulated the highest density of YOY frogs observed at our study during late August 2012, when detectability trials were conducted (Anderson 2013). Location of transects was established using a 15 m-long throwing line (Northwater© "Small Regulation Throw Bag"), and decoys were tossed onto a transect from a few meters to one side to avoid trampling vegetation. Two surveyors, unfamiliar with the location and the number of decoys, were allowed up to 4 minutes to search the 15 m transect (Fig. 3). This pace was similar to that of visual encounter surveys for live frogs. Over 3 days, we conducted searches of 26 transects in each habitat type (i.e., pond shorelines and beaver canals), on three ponds (6, 10, and 10 transects per pond as dictated by pond size), requiring a total of approximately 36 person-hours. Searches were timed, and the proportion of decoys recovered was corrected for search time, standardized to 4 minutes. Using a similar approach to Dong Saul (2008), the probability of detecting decoys was calculated as:

$$p(D) = \frac{N \text{ decoys recovered}}{15 \text{ decoys available}} \times \frac{240 \text{ seconds}}{\text{Search time in seconds}}$$

Mackenzie and Kendall (2002) present reasons for believing *a priori* that detection probabilities differ among sampling episodes, and suggest that where such a difference is not documented, it is more likely the result of low statistical power than equivalence of detection probability. Therefore, we used an alpha value of 0.10, following methods used by Skalski et al. (1983),

FIG. 1. Comparison of a decoy (left) and young-of-the-year Wood Frog (right). Note the bead that mimics an eye, and the shallow ridge that mimics one of the dorso-lateral ridges of a ranid frog.

FIG. 2. Frog decoy (SUL = 28 mm). A third bead (not visible) was glued to the other side of the decoy's head, and the half toothpick mimics a leg.

FIG. 3. Surveyors searching vegetation for frog decoys along a beaver canal in Miquelon Lake Provincial Park, Alberta, Canada.

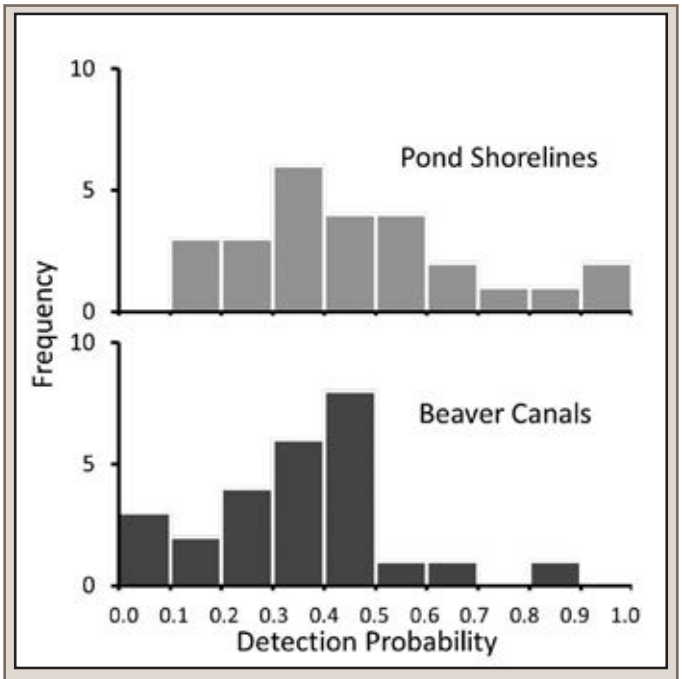

FIG. 4. Frequency histograms of the probability of detecting decoy frogs on 26 transects in each of two habitat types, in Miquelon Lake Provincial Park, AB.

to increase the power of our design and reduce the risk of type II error, *i.e.* concluding that there is no difference in detectability when a difference actually exists. We tested for a difference in mean detection probability between the two habitat types using a paired *t*-test. Detection probability for frog decoys averaged 0.45 (ranging from 0.13 to 0.97) along pond shorelines and 0.35 (ranging from 0.06 to 0.65) along beaver canals (Fig. 4). Detection probability differed significantly between the two habitats ($t_{25} = 2.000$, $p = 0.056$), thus we recommend that CPUE of live frogs for each of these habitat type should be divided by its respective *p(D)* before making any comparison of abundance between habitats. However, the statistical power for our trials was only 0.617 (based on $n = 26$, $\Delta\bar{x} = 0.108$, $s = 0.2756$, $\alpha = 0.10$; using the "stats" package in R version 2.15.1, R Core Team, 2012). If we had not detected a significant difference in *p(D)* between the two habitats, we would not have been able to conclude that *p(D)* was equal without a larger sample size than the 26 trials we conducted (at $\beta = 0.10$, $n = 58$, calculated as previously).

We propose that our approach be applied to visual transect surveys for other fairly conspicuous amphibians or reptiles to increase the accuracy of resultant abundance estimates. However, the fact that decoys do not move should be taken into consideration. Decoy searches may not be realistic if movement strongly affects detectability. Daily or seasonal activity patterns of the study organism should also be considered before using decoy searches, as this technique is best suited to estimating the detectability of animals that are moving on the surface of substrates rather than hiding in refugia. For example, although wood frogs are conspicuous during post-metamorphic dispersal in August, they burrow under leaf litter in fall prior to overwintering (Russell and Bauer 2000).

Using decoys is a simple, inexpensive alternative to using live animals to estimate detection probability and for improving the quality of survey data. Decoy searches can be completed within a short time span in the same locations as visual transect surveys for live animals, and by the same surveyors. We recommend researchers use decoy searches to produce detection probabilities specific for the species, system, and questions under study.

Pioneering the Utility of a Mineral Oil Mixture for Fluorescent Powder Tracking of Salamanders

The movement patterns of amphibians are important to our understanding of population ecology and behavior. The development of new tracking methods and the improvement of existing methods for amphibians will be valuable for determining the behavior of small amphibians. New tracking methods also will be a crucial component to conservation of amphibian species worldwide. Techniques for tracking behavior of small salamanders are currently quite limited; modern radio-tracking devices are still too large and thread-bobbin techniques are inappropriate for fossorial species (Graeter and Rothermel 2007). Although Passive Integrated Transponders (PIT) tags have been used successfully for some salamander species (Charney et al. 2010; Connette and Semlitsch 2012; Hamed et al. 2008), these have limitations and in some cases fine-scale tracking may be limited.

Fluorescent powder is considered a safe option for tracking small animals (Orlofske et al. 2009; Rittenhouse et al. 2006; Roe and Grayson 2009; Stapp et al. 1994) including snakes, lizards, frogs, and salamanders (Birchfield and Deters 2005; Dodd 1992; Eggert 2002; Furman et al. 2011; Graeter 2005; Stark et al. 2005). A method described by Eggert (2002) combined mineral oil and fluorescent powder as a tracking medium for toads. This medium was reported to improve tracking efforts for spadefoot toads (*Pelobates fuscus*) (Eggert 2002). We wanted to determine whether the addition of mineral oil to fluorescent powder could increase our ability to track salamanders. To our knowledge this technique has not been tested on any other amphibian species, and its only other application was as a tracking medium on track plates associated with drift fences (Popescu and Hunter 2011). Before using this technique in the field, we wanted to determine whether it caused salamanders to react adversely. We chose the Red-backed Salamander (*Plethodon cinereus*) as a study species because it respires cutaneously, likely making its skin more sensitive to the application of any substance. Also, we examined Eggert's (2002) suggestion that the addition of mineral oil to fluorescent powder would increase the distance animals can be tracked. We expected that the mineral oil would improve track length, especially under rainy conditions when many salamanders are most active.

Materials and Methods

Short-term survival and condition.—We captured Red-backed Salamanders in the Jefferson National Forest near Pembroke, Giles Co., Virginia, USA. Thirty, non egg-guarding adults were captured in the first week of June 2012 with no preference to color morph. Each salamander was housed in an individual sealable plastic bag (17 cm × 17 cm) with moist leaf litter collected at their capture location. Animals were weighed fully hydrated, directly after removal from moist housing. During the entire experiment all individuals were kept in coolers with temperatures ranging from 5–15°C (but tested at room temperature, approximately 20°C). Salamanders were not fed during the experiment but small invertebrates may have been present in the leaf litter.

Before the experiment began each individual was weighed using an Ohaus Scout II portable electronic balance accurate to 0.01 g. For the experiment, individuals were divided into control (N = 15) or treatment (N = 15) groups by random stratified sampling according to their weight. The treatment group had a mixture measured by volume of one part mineral oil (Sigma-Aldrich: Sterile-filtered, BioXtra, suitable for mouse embryo cell culture, Light oil neat) and two parts fluorescent powder (Day Glo Color Corporation: ECO formaldehyde-free fluorescent pigment, Blaze Orange ECO-15,) and was applied with a sterile cotton swab primarily to their legs. Control group individuals were treated in the same way except distilled water was applied instead of the oil and powder mixture. All individuals were placed in clean plastic bags that contained moist unbleached paper towels for the duration of the experiment.They remained in these bags for 12 h, and every 3 h a visual inspection of general health was conducted. After 12 h the treatment group was cleaned using sterile dry wipes to remove any remaining oil/powder and the control group was also wiped. Once all powder was removed the animals were returned to their original bags containing leaf litter for a three day monitoring phase. We checked animals once every 24 h following the experiment. Inspections for physical abnormalities were conducted and each salamander's righting response was confirmed by placing the animal on its back and observing behavior. At the end of the experiment each animal was weighed and measured again, then returned to its original capture location. We used a two tailed t-test assuming unequal variances to examine differences in weight loss between the two groups.

Tracking Efficacy.—We evaluated the interaction of the rain and the utility of plain powder compared to mineral oil and powder mixture. For this test, we did not use live animals, but instead, we cut carrots to even sizes (30 mm × 5 mm × 5 mm), tied a string to them, and pulled them through a substrate of mowed grass (pasture or lawn) 2.5–12.7 cm tall. These paths were marked only at the beginning and measured 65 m long. Carrots either had plain (N = 20 paths) fluorescent powder or a mixture (N = 20 paths) of mineral oil and fluorescent powder (1:2 ratio by volume respectively) applied to approximately 90% of the surface of each carrot. We returned to the paths at night, used the marker placed at the start, and followed each trail until we could no longer detect the fluorescent powder. We used a VI Light (Northwest Marine Technologies, Inc.) to determine the path left by the fluorescent powder and oil-powder mixture. The end of a path was declared when all visible fluorescent powder was absent and the researcher could not confidently determine a further path of travel. We used multiple observers to determine visible path length. Paths were assigned to observers in pairs, so that every observer measured equal numbers of powder only and oil-powder mixture trails. The mineral oil altered the texture and color shade of the fluorescent track, so observers were not blind to the different treatments. During our experiment light rain (~ 2 cm) occurred between the dragging and measuring of 20 trails (10 powder, 10 oil/powder). Rain did not occur between the dragging and measuring of the other 20 trails (10 powder, 10 oil/powder). We used an Analysis of Variance (ANOVA) to evaluate whether the length of a track was different when using powder only or the oil/powder mixture, if rain changed this relationship, and the interaction of rainfall and type of tracking medium. A Tukey HSD was used to evaluate pairwise comparisons. Data from both experiments were analyzed using the statistical analysis software JMP®10 (SAS Institute Inc., Cary, North Carolina) and we set the α-level at 0.05.

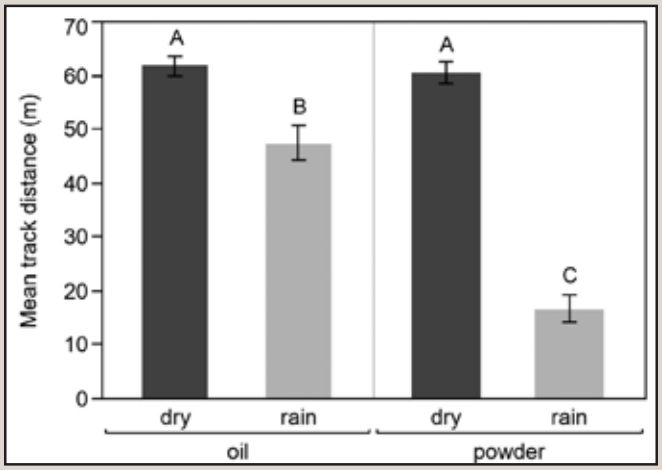

FIG. 1. Interaction between type of tracking medium (powder or oil powder/mixture) and presence (rain) or absence (dry) of rainfall on the distance of tracks through grass (if not connected by the same letter then groups are significantly different).

RESULTS

All salamanders remained alive in both the mineral oil group and the control group. Weight loss during the experiment was small and there was no difference between the control and treatment groups ($t_{df=14} = 1.92$, SE= 0.012, P = 0.06). Overall, the treatment group had a mean weight loss of 0.02g and the control group had a mean weight loss of 0.07g. During the experimental and monitoring phase of our procedure no animals displayed injury and all animals exhibited the ability to right themselves.

The overall ANOVA model was statistically significant ($F_{df=3,36}$= 72.68, P = <0.001), and the interaction between rainfall and marking treatment was also statistically significant ($F_{df=1,36}$= 35.93, P = <0.001; Fig. 1). The Tukey HSD indicated that when conditions were dry the length of tracks from powder only and the oil powder mixture did not differ. Both media left visible tracks for a mean distance of greater than 60 m (over 93% of the course) in dry conditions. If rain occurred following the track being laid down then the length of the track declined for both media. However, following rain, the tracks using the oil/powder mixture were significantly longer ($\bar{x}$ = 47.39 m) than tracks using powder alone ($\bar{x}$ = 16.71 m) (Fig. 1).

DISCUSSION

Before considering the use of mineral oil on wild salamanders, we wanted to ensure that it did not cause any behavioral changes or affect the condition of salamanders. When observing salamanders with the oil/powder mixture, we saw no unusual behaviors (such as attempting to wipe off the mixture), and no reduction in the ability to right themselves. In the three days they were monitored after treatment, we documented no mortality, no skin abnormalities, and no significant weight loss. The weight loss between the treatment and control groups was somewhat different, however not significantly, and a larger sample size may have improved the clarity of this result, but overall weight change was minimal for all animals. These results suggest that there are no short-term negative effects of applying a mixture of mineral oil and fluorescent powder to the legs of plethodontid salamanders. Applying mineral oil to a greater proportion of the body surface

of an animal may have a different effect, as it could interfere with water absorption or respiration. Future study could use a respirometer to measure differences in oxygen consumption (e.g., Orlofske et al. 2009). Documenting rates of water loss and gain would also be of interest. We did not have the opportunity to follow animals in the field to examine how long the oil/powder mixture would remain on the animal. Given that much of the mixture had worn off the salamanders during the 12-hour period when they were enclosed in a resealable bag, we expect that in the field the mixture would not persist more than 24 h.

Although tracks left by amphibians will certainly differ from those left by carrots, we used this technique to assess track length under controlled field conditions. We were not yet ready to apply the oil to wild salamanders as the effect of leaving the mixture on for longer periods of time was still unknown. We found that using the oil-powder mixture allows us to follow tracks for almost three times the distance of plain powder tracks when tracks were exposed to rain. We believe this technique has enough value to warrant further study. Fluorescent tracking can be used in concert with other tracking methods and will allow scientists to collect more detailed movement data on target species.

Acknowledgments.—We thank the Fralin Summer Undergraduate Research Fellowship program for support throughout this project. Several people assisted with data collection and proofing including Matthew Bragg, Houston Chandler, Rebecca Frankel, Anna Louise Haas, Jianong (Canna) Mao, A. Dawn Mercer, Genevieve Pegram, Christine Proctor, and Antonio Tacilla Villanueva. Lisa Beebe helped us to translate a message into French for Christophe Eggert, and he supplied us with photos of and advice about when he added mineral oil to fluorescent powder to track *Pelobates fuscus*. Fluorescent powder was donated by Day Glo Color Corporation. We received support for other materials and supplies as part of ongoing amphibian monitoring projects at Eglin Air Force Base. All procedures were approved by Virginia Tech's Institutional Animal Care and Use Committee and all necessary state and federal permits were obtained.

Use of Stationary Microchip Reader for Monitoring Interpond Movement of Freshwater Turtles

Studying overland movement patterns of freshwater turtles is critical to understanding population dynamics and establishing buffer zones for species protection (Bodie 2001; Burke and Gibbons 1995; Semlitsch and Bodie 2003). Numerous methods have been applied to investigate different aspects of the movement patterns for freshwater turtles (McDiarmid et al. 2011) such as pitfall traps (e.g., Gibbons 1990; Roe et al. 2009), radio telemetry (e.g., Forsythe et al. 2004; Litzgus et al. 2004), and traditional aquatic trapping methods (e.g., crab pots and hoop nets; House et al. 2010; Roe and Georges 2008; Thomas and Parker 2000). Terrestrial and aquatic traps are associated with capture-mark-recapture techniques that rely on the ability to recapture marked turtles. Trapping is usually seasonal or done at intervals, but rarely conducted continuously, or if so not on a long-term basis (e.g., every day of the year during multiple years). Traps are usually checked daily, but the information on specific times of the day that turtles are likely to be active is lacking. In addition, captured individuals

IVANA MALI*

**Corresponding author; e-mail: im1040@txstate.edu*

remain in traps until the traps are checked, preventing movement or dispersal data aside from differing points of recapture. Radio telemetry can give more precise data on the overland activity and correlate such activity to environmental factors (Roe and Georges 2008). However, the radio tracking period affects such models (Roe and Georges 2008) and high-resolution monitoring of overland activity using radio telemetry would require locating turtles several times/day for extended periods of time.

Passive integrated transponders (PIT) have usually been associated with capture-mark-recapture techniques. However, the technology has evolved to afford identification with stationary readers, reducing the labor to only capture-mark because animals do not have to be physically recaptured, they need only to pass through the stationary reading system. The system has been applied to monitoring the use of drain culverts by desert tortoises (Boarman et al. 1998), monitoring fish through small stream passages (Zydlewski et al. 2007), and monitoring bat movements (Ellison et al. 2007). The purpose of the present study was to test the utility of the stationary PIT tag reader for recording the overland activity of freshwater turtles. We introduce PIT tags and non-invasive stationary reader system for monitoring interpond movement of freshwater turtles, including the addition of camera traps for assisting in determining the direction of the movement alongside detection of individuals. We sought to create a less labor intensive and simultaneously less invasive approach to studying overland activity of freshwater turtles.

Materials and Methods.—For the stationary PIT tag reading system, we used Biomark© Portable Transceiver System, model FS2001F-ISO, that has the ability to store scanned tag codes. This model is not traditionally used as a stationary system; therefore, we purchased the Elpac AC power supply to provide continuous power to the reader. We used the Biomark© OEM Racket Antenna with Line-X coating for durable protection and a 2-m antenna cable. To mark turtles, we used 12-mm AVID© PIT tags. Although the tags and the reader were produced by two different manufacturers, the tags were not encrypted by the producer and the reader was able to recognize the codes. In addition, we used a RECONYX© game camera in order to get images of the turtles as they were passing through the system.

This study was conducted in a complex of ponds within a 7-ha private property parcel in Guadalupe County, Texas (Fig. 1). The primary system includes four ponds that are completely fenced off with a 2 cm × 4 cm horse fence panels that enabled us to restrict global overland movement of adult turtles in and out of the system by opening or closing a series of gates. This primary system is surrounded by a third-order ephemeral stream and three additional ponds. In our initial test of the enclosure system, one pond (Enclosure Pond 1; Fig. 1) was fenced off from the remaining ponds using 152-cm vertical horse panels with 5 cm × 10 cm openings. The Enclosure Pond 1 was pumped dry in the spring of 2009 in order to allow complete removal of turtles to enable this investigation. After the turtles were removed, the pond was visited for an additional week. To ensure there were no turtles left, we searched for tracks exiting the pond or the mud and conducted hand searches of the mud itself. The pond was then refilled and a single unmarked turtle (juvenile male *Trachemys scripta*) was released into the pond. For the months following, no other turtles were observed in the system, but the introduced male was routinely observed basking or at the pond's surface confirming that the pond perimeter fencing was "turtle-proof." In addition, we regularly inspected the fence to ensure its integrity. Then a single 0.36 m × 0.2 m "turtle gate" was created,

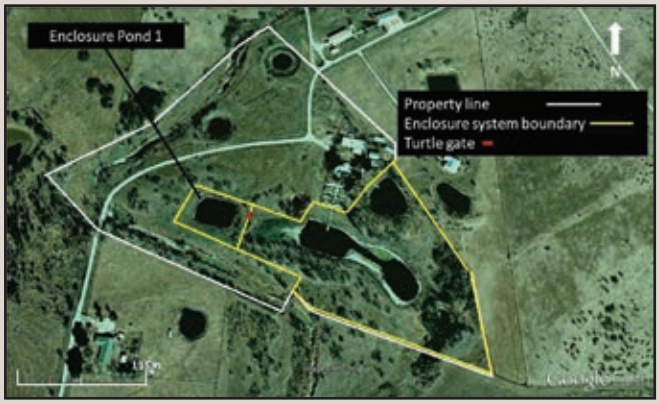

FIG. 1. Aerial image of the study area used to monitor the interpond movement of freshwater turtles. The image shows the enclosure system boundary (primary system) that includes 4 ponds that are completely fenced off with a 2 cm × 4 cm horse fence panels to restrict global overland movement of turtles in and out of the system. In addition, Enclosure Pond 1 was fenced off from the remaining ponds, with a single opening allowing movement (turtle gate).

FIG. 2. Stationary reader system placed at the only opening (turtle gate) of otherwise enclosed area (Enclosure Pond 1). While the reader scanned PIT-tagged turtles that pass through the gate, the game camera recorded the images and the direction of the movement.

enabling interpond turtle movement. In this gate opening we placed the reader antenna just subsurface within the gate. We placed the rest of the reader in a dry box on the shelf built next to the gate to enable long-term protection (Fig. 2). The reader was connected to the power source located ~50 m from the gate using an outdoor run of 120V A/C. We mounted the game camera 1 m vertically above the gate opening and parallel to the ground.

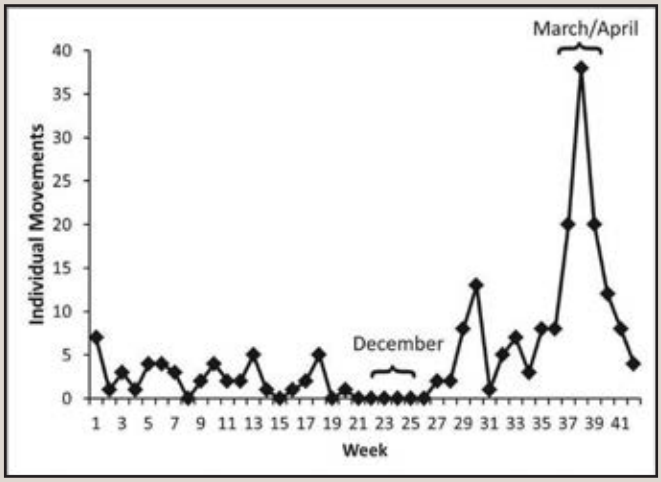

FIG. 3. Number of individual movements recorded by the stationary chip reader sorted by the week since opening the turtle gate in July 2011. The movement activity was seasonal, with very few movements in the winter and the highest activity in spring.

FIG. 4. Red-eared Slider (*Trachemys scripta elegans*) passing through the turtle gate. The image was captured with a RECONYX© game camera that was mounted 1 m vertically above the gate opening.

In the spring of 2011, we captured turtles from the primary and secondary pond systems using baited hoop nets and used the captures to populate Enclosure Pond 1. We PIT tagged captured turtles by injecting the chips into the body cavity in the anterior inguinal region parallel to the spine (Buhlmann and Tuberville 1998). We tagged two Texas Spiny Softshells (*Apalone spinifera emoryi*), four Texas River Cooters (*Pseudemys texana*), and 57 Red-eared Sliders (*Trachemys scripta elegans*). The turtle gate was kept closed for a period of one month after the "stocking" event in an effort to prevent disturbance-related dispersal and then opened in July 2011. This initial test of the system then continued to March of 2012 (9 months).

Results.—The reader proved to be a reliable method for recording the passage of turtles through the gate. For example, within the first 9 months, 46 PIT-tagged turtles (73% of all chipped turtles) passed through the gate and were recorded by the reader on 105 different occasions. Movement did not appear to be sex biased: 23 females, 22 males, and one juvenile were recorded. The number of individuals' movements varied from 1–12. Twenty-eight turtles moved on only one occasion while 18 moved more than once. Six individuals moved in and out of the system on several occasions during a single day (range = 2–4, mean = 2.3). Preliminary results revealed predictable seasonal activity in winter, with 0–1 movement events per week, and highest activity in the spring, with up to 37 passages per week (Fig. 3). All turtles were active during the day, with no nocturnal activities recorded. Out of 105 movement occasions, 42 were recorded in the morning (0630 to 1200 h DST) and 63 in the afternoon (1200 to 2030 h DST). Based on the original placement of tagged turtles (Enclosure Pond 1), we could speculate on the direction of the movement. However, because the reader was set to continuously record the tags, the data often consisted of numerous readings of the same tag within a short period of time (several minutes), which created some level of uncertainty of the final direction of the movement using the reader alone. However, the combination of the chip reader and the camera recording the time enabled us to validate the direction of the movement of each tagged turtle using the camera images (Fig. 4). The camera recorded 31 additional images of untagged turtles.

Discussion.—We demonstrated that it is simple and useful to convert a portable Biomark© chip reader system into a stationary PIT tag reader system enabling us to monitor freshwater turtle interpond movement. This technique requires initial trapping and PIT tagging individual turtles, however it is a subsequently noninvasive way to study fine-scale movement patterns. It is less labor intensive than either consistent trapping or long-term radio telemetry, and if the equipment is properly maintained, the system can run for extended periods of time (several years). Although the reader did not record the exact times turtles exited the water bodies but rather the times of the passage through the gate, this method is likely to be a suitable way to link weather conditions and periods of the day to the turtle movement patterns.

Our study was conducted on a private property with a nearby access to an electric power source. One way to improve this system would be to use solar energy as a source of power, especially for monitoring projects in more remote areas. We constructed only one reader station and used a relatively small enclosed area for proof of concept testing. Our study potentially underestimated the magnitude of movement, due to the possibility that some individuals did not walk along the fence but rather returned to the water. We believe that such occurrence was minimal, due to the small scale of the experiment (e.g., small fence perimeter) and the fence was simply serving the role of the aluminum flashing in commonly used drift fences (Gibbons 1990). This system was designed to be expanded using additional gates that open the primary system to the secondary system and allow the movement between the ephemeral creek and the additional ponds. On even larger landscape level, monitoring movement in this manner would be costly, because it would require enclosing larger sections and purchasing additional chip readers and PIT tags. However, high-resolution interpond movement dynamics of freshwater turtles on a larger landscape level are still poorly understood and expanding this approach to a larger scale could be useful in contributing to the understanding of these movement patterns.

For the resolution we sought on the dynamics of movement, other alternative methods are actually more expensive. For example, while radio telemetry would address these same questions, the labor costs and implementation necessity for shift work across 24-h, everyday schedules is dramatically (and prohibitively) more costly. We evaluated alternatives to achieving the same level of data intensity prior to this installation. One way to reduce the cost for a larger-scale study would be to modify

the way the area is enclosed. For example, Gibbons (1990) used aluminum flashing to enclose several miles of perimeter of experimental water bodies in order to study the interpond movement of slider turtles. Therefore, instead of using a costly fence system, one could use aluminum flashing that is commonly incorporated during the construction of drift fences, with pitfall buckets being replaced with reader systems. Unfortunately, this alternative has its own trade-offs. We consider flashing to be very disadvantageous in its relative instability to tree fall, livestock, and vehicular passage, all of which are overcome using fencing. Further, the urban wildland interface in many states provides an opportunity to create larger scale studies that follow our new approach with relatively minor changes to existing fencing systems (bottom integrity, gate installation, and readers). All methods seeking to document wild animal movements in real time have tradeoffs. We consider this new approach to minimize several negative aspects of radio telemetry costs and provide data at a finer resolution than can be achieved by other methods. Even in the study by Gibbons (1990), once trapped, the animals were contained until release, while in our system they are constrained in an exit point but not in movement beyond that single constraint. While this too is a tradeoff, we argue that it is a lesser one than daily point observations from telemetry or daily capture locations in a large field enclosure with pitfalls.

Acknowledgments.—We thank D. J. Brown and M. C. Jones for assistance with PIT tagging. Texas Fence LLC was crucial to the placement and construction of the "turtleproof" fencing. This study was conducted under Texas Parks and Wildlife Department (TPWD) Permit SPR-0102-191 and funded by the TPWD in its evaluation of turtle harvest impacts within Texas. This research was approved by the Texas State University-San Marcos Institutional Animal Care and Use Committee (protocol 1010_0501_09).

Use of Clove Oil as an Anesthetic for PIT Tagging and Surgery with the Three-toed Amphiuma (*Amphiuma tridactylum*) and Determination of Recovery Time as a Function of Body Mass

Amphiuma tridactylum is a large (up to 1 m and 1.5 kg), slimy, aquatic salamander that can deliver a powerful bite, and thus is difficult and potentially dangerous to handle (Fontenot 1999; Fontenot and Seigel 2008). Even simple tasks like PIT (Passive Integrated Transponder) tag implantation and measuring body length are virtually impossible without restraining the animal. Physical restraint is undesirable because it can result in skin abrasion, physical trauma to internal organs (e.g., liver damage), and potentially death. Using a plastic snake tube to restrain *Amphiuma* (Brown and Forstner 2009) can facilitate handling *Amphiuma* in the field, but is of limited use for accurate body

measuring, examining specimens closely, or PIT tagging because the salamanders do not relax and straighten their bodies, and are slimy and impossible to gently restrain by hand. The slippery mucus, reduced limbs, and long cylindrical shape of *Amphiuma* make forced restraint extremely difficult, even with techniques like the "bender" board (Burgmeier et al. 2010). Pojman Sr. et al. (2011) reported immersion in ice water and exposure to isoflurane as effective methods for immobilizing *Amphiuma* for PIT tagging. Immersion in ice water is effective for immobilizing to perform physical measurements and PIT tagging, but it is not suitable for surgery. A variety of anesthetics has been used with amphibians with varying effectiveness and duration of anesthesia, including zolazepam, methoxyflurane, isoflurane, propofol, tricaine methanesulfonate, barbiturates, clove oil, etc. (Lafortune et al. 2001; Mitchell 2009). In addition to efficacy, anesthetic choice may also depend on ease and safety of application. For example, isoflurane may be effective, but it is expensive, difficult to apply (particularly in the field), and its vapors pose a hazard to the investigator. Application of other anesthetics by injection may not be possible in subjects that are difficult to temporarily restrain (e.g., large slimy salamanders).

The phenolic compound eugenol, the active component of clove oil, is an effective anesthetic for amphibians, and can be applied by immersion, potentially making it suitable for work in the field with species that are difficult to handle. However, duration of anesthesia was greater in larger individuals of African Clawed Frogs (*Xenopus laevis*; Goulet et al. 2010). To assess the utility of clove oil as a cheap and readily available anesthetic for *A. tridactylum*, as well as the effect of body size on recovery time, we anaesthetized individuals of various body sizes via submergence in a clove oil solution.

Methods.—Seventeen *A. tridactylum* were collected with baited flexible fish traps (Promar 36 inches × 12 inches with ¼-inch mesh) in East Baton Rouge Parish, Louisiana, USA. Specimens were weighed and measured, and maintained in laboratory aquaria at 25°C and fed one earthworm per day each for 1–3 days, except for two individuals that were maintained for six months and two years, respectively, and one extremely large specimen maintained in captivity for eight years. Experimental trials were conducted February–May 2012, and solutions were prepared from the same bottle of clove oil. Each specimen was placed separately in a solution containing 4 L of water with 2 mL of clove oil for five minutes. Because preliminary observations suggested that eugenol continued to be absorbed from the skin after removal from the solution (i.e., degree of anesthesia increased), the specimen was removed to another container without water for twenty minutes, and then a PIT tag was inserted by subcutaneous injection (except two individuals). After the 20-minute waiting period, the specimen was placed in 10 L of tap water in a cooler. All water and solutions were at 24 ± 2°C. Every 15 minutes, the individual was removed and placed ventral side up to test their righting response. When the animal was able to right itself, it was determined to have recovered.

Six additional specimens, with masses ranging from 140 g to 450 g, were used to test the minimum exposure required to achieve surgical anesthesia, which was determined by the time until specimen did not respond to needle poke in the tail.

Because visual inspection of a scatter plot suggested two distinct trends, we used a piecewise regression to determine the relationship between body mass (x-axis) and recovery time (y-axis). As a basis for dividing the data into two sets (A and B) for the piecewise regression, we sought to identify a breakpoint that explained the most variance (highest R^2 values) for a pair of regressions. We began with a regression analysis on data set A, which was composed of the five smallest individuals, and then on data set B composed of the remaining 14 (larger) individuals. For the next statistical trial, we moved the next larger individual (from set B) into set A, and repeated the regressions. Natural log transformation was applied to both body mass and recovery time, to meet assumptions of regression analysis. Alpha for significance was 0.05.

Results.—For the first 2–3 minutes in the solution, individuals often were agitated, swimming back and forth quickly in the container. By five minutes, the animals were sufficiently sedated that they could be easily picked up by hand and transferred to another container (though they were still mobile and could right themselves. At five minutes of exposure to the clove oil solution, individuals were sufficiently anesthetized to allow easy handling, and some had already lost the righting response. After the 20-minute waiting period, none had a righting response, and each was completely limp (Fig. 1).

We were initially concerned that individuals might drown while still under anesthesia during the recovery period. However, they did not attempt to breathe until their heads were raised above the water when we checked for a righting response. Each time the head was raised above the water surface, it took a breath.

Piecewise regression showed two distinct relationships between body mass and recovery time. Recovery time increased with body mass for individuals that were 19–365 g ($N = 13$, df, = 1, 11, $F = 20.19$, $P = 0.0009$, $R^2 = 0.65$), and decreased sharply for individuals that were 540–3185 g ($N = 6$, df, = 1, 5, $F = 31.38$, $P = 0.025$, $R^2 = 0.86$), suggesting a body mass threshold at some point between 365–540 g for this effect (Fig. 2).

Surgical anesthesia was achieved for all six specimens by a 10-minute exposure to the clove oil-water solution followed by a 20-minute waiting period out of water.

Discussion.—Clove oil is an inexpensive, highly effective, anesthetic for *A. tridactylum*. The exposure time used in this study was sufficient to induce anesthesia at a level suitable for simple noninvasive tasks like taking measurements, or minimally invasive tasks like PIT tag insertion. However, an exposure time of at least 10 minutes to the same solution was required for a level of anesthesia suitable for invasive tasks like intraperitoneal surgery, which we used successfully for transmitter implantation in an ongoing study.

Our dosages were comparable to those reported for other amphibians. Mitchell et al. (2009) used 450 mg/L for Tiger Salamanders (*Ambystoma tigrinum).* They also achieved surgical anesthesia after a 10-minute exposure. Guénette et al. (2007) used eugenol, the active component of clove oil, with *Xenopus laevis.* They found immersion in a bath with 350 mg/L for 15 minutes achieved surgical anesthesia.

The rate of diffusion of the anesthetic into/out of the body of the animals is proportional to the surface area, in this case, of the skin. Because surface/volume ratio decreases with increasing body size, larger animals would be expected to take longer to absorb enough eugenol to reach anesthesia, and longer to expel it by diffusion during recovery, i.e., recovery rate should be inversely proportional to the surface area to volume ratio. However, the fact that the positive relationship was only true for individuals up to 365 g, and reversed for individuals greater than 590 g is puzzling. It might indicate some threshold limiting diffusion, e.g., skin permeability or allometric differences in physiology, and certainly warrants further investigation.

Acknowledgments.—The methods used in this work follow guidelines of the Society for the Study of Amphibians and Reptiles and were approved by the Animal Care Committee at SLU (IACUC, Protocol #0015) and LSU (protocol number 09-072). We thank Barbara Corbett Kermeen of AVM Instrument Company, Ltd. for help with the transmitters. We also thank Brad Lavigne and Julia Morris of the Tickfaw State Park Nature Center for allowing us to make measurements on their specimen.

AMPHIBIAN DISEASES

This section offers a timely outlet for streamlined presentation of research exploring the geographic distribution, host range, and impact of emerging amphibian pathogens, especially the amphibian chytrid fungus *Batrachochytrium dendrobatidis* (*Bd*) and ranaviruses. *Bd* is an emerging pathogen linked to mass mortality and declines of amphibians worldwide, yet *Bd* has also been detected in amphibians without disease. Ranaviruses also cause mass mortality, but have not yet been linked to large-scale declines. We know relatively little about their global distribution, host range, or impacts on host populations. To improve our understanding of the scope of this issue, we encourage submission of studies that illuminate the geographic distribution, host ranges, and impact of these pathogens on amphibian populations, including research on individual species or groups of species, wild or captive animals, native or non-native species, live animals or museum specimens, environmental samples, and, provided there is sufficient sampling[1], reports of non-detections.

We ask authors to: 1) restrict the Introduction of their paper to a **maximum** of two paragraphs to highlight the context of their study; 2) briefly include both field and laboratory Methods; 3) present Results in a Table, although a map might also be useful, and limited text; and 4) have a short Discussion of a **maximum** of three paragraphs to touch upon key findings. Please include the following information in submissions as appropriate: coordinates and description of sampling areas (or please note if locations are extremely sensitive to reveal, and provide general area instead); species name(s) and life history stages examined, as well as other species present; whether samples were collected randomly or just from dead or moribund animals; date of specimen collection; evidence of unusual mortality; numbers of positive and negative samples; disposition of voucher specimens; name of collaborative laboratory or researcher conducting histological sections or PCR analyses; and names of cooperative land owners or land management agencies. We encourage researchers to conduct post-mortem examinations when possible to identify the cause of death when reporting mortalities. We aim to expedite the review and publication process! Please e-mail *Bd*-focused submissions directly to Associate Editor, Dr. Dede Olson: dedeolson@fs.fed.us. Manuscripts concerning ranaviruses should be directed to Associate Editor Dr. Jesse L. Brunner: jesse.brunner@wsu.edu.

[1] If a sample of thirty individuals of a particular life history stage of a particular species yields no positive results, and the diagnostic test is highly sensitive, one can conclude that the prevalence of infection is less than 10% with 95% confidence. With a sample of 10, an infection in one of four individuals could go undetected. We encourage researchers to collect sufficient samples so that negative results are meaningful.

Understanding Patterns of Amphibian Chytrid Fungus Infection and Chytridiomycosis through Museum Collections: Maximizing Sampling and Minimizing Damage on Preserved Specimens

For centuries, collections in natural history museums have been essential databases that have given an historical perspective of the distribution, diversity, and general biology of species in space and time. These collections also contain critical data for understanding ecosystem dynamics and for decision-making in the conservation of biodiversity (Cotterill 1995, 1997; Graham et al. 2004). Museum collections are highly valuable tools for documenting our planet's biodiversity, especially when so many species are going extinct, such as the Golden Toad (*Incilius periglenes*) in the highlands of Costa Rica, last observed in the late 1980s (Crump et al. 1992). In recent years, museum specimens have been used as sources of genetic sampling, which is particularly valuable when the collection of new samples becomes difficult or impossible, because the study species is extinct (Payne and Sorenson 2003). Museum collections also substantially

contribute to the study of pathogens, disease vectors, and environmental pollutants (Suarez and Tsutsui 2004).

Amphibians are declining faster than birds and mammals, giving this group of animals the distinction of being the most threatened major taxonomic group of vertebrates (Stuart et al. 2004; Wake and Vredenburg 2008; Hoffman et al. 2010). One of the possible contributing factors to amphibian losses is the disease chytridiomycosis, caused by the fungal pathogen *Batrachochytrium dendrobatidis* (*Bd*) (Berger et al. 1998; Pessier et al. 1999). Museum collections have a role in understanding the emergence of *Bd*. The existence of herpetological collections in museums around the world has aided identification of the spatio-temporal distribution of *Bd* in many regions (e.g., Ouellet et al. 2004; Puschendorf et al. 2006; Velásquez et al. 2008; Padgett-Flohr and Hopkins 2009), as well as providing support for routes of the pathogen's dispersal through Central and South America (Lips et al. 2006; Lips et al. 2008; Vredenburg et al. 2010; Cheng et al. 2011). In addition, these collections have provided evidence that *Bd* has long been in Africa (Weldon et al. 2004; Soto-Azat et al. 2010), Japan (Goka et al. 2009), and North America (Garner et al. 2006; Padgett-Flohr and Hopkins 2009), facilitating the evaluation of possible sites of the pathogen's introduction to some regions.

Museum curators have conflicting mandates between retention of specimen integrity as a source of scientific information versus specimen uses to aid species conservation efforts (Graves and Braun 1992). Whereas there is a mandate to keep specimens intact, it is also becoming increasingly apparent that they may be useful to gain information that could be vital for preservation of biodiversity, yet that might involve techniques that can inflict damage to specimens. Curators have coined the term "destructive sampling" for the use of skin samples obtained from museums specimens (Graves and Braun 1992), with amphibian skin being of particular interest to scientists interested in *Bd* research.

To address this situation and minimize the conflict many curators experience, we suggest herein a technique for obtaining skin biopsies to diagnose *Bd* infection of museum specimens. We propose the use of a skin biopsy punch (Fig. 1), a commonly used instrument in veterinary medicine. The advantage of using this instrument is that it has a one-piece cutting blade (not seam rolled) to ensure a clean cut, is easy to manipulate due to its lightweight handle, and is available in different diameters for the cutting area (from 1.5 to 8.0 mm). If standardized, this single-punch approach could limit the destructive sampling of museum resources while facilitating comparative studies.

The pelvic patch of the animal is an optimal sampling area for several reasons. First, anurans absorb water from a wet surface only through the ventral skin (Wells 2007), hence this part of anatomy is likely to be in contact with water, where *Bd* zoospores may be free-living. The skin of the ventral region (pelvic patch) has a greater density of blood vessels than the skin of the chest or back, which is consistent among species (Wells 2007), and which could facilitate diagnoses of chytridiomycosis symptoms. The pelvic patch usually exhibits greater osmotic flows than the skin from other ventral regions, which in turn have greater osmotic flow than the dorsal skin (Wells 2007). Disruption of this osmotic flow may occur with *Bd* infection (Voyles et al. 2009), and symptoms of chytridiomycosis include skin tissue anomalies. The pelvic patch has the biggest propensity to become infected with *Bd*; therefore, it is the best area to identify the presence of *Bd*

via histopathology (Puschendorf and Bolaños 2006). The pelvic patch is an anatomical area that facilitates standardization of sampling, as discussed below. Hence, examination of the pelvic patch allows researchers to evaluate not only possible infection by *Bd*, but also the existence of histopathological changes that may compromise the animal's life as symptoms of chytridiomycosis develop (Wells 2007).

Our technique consists of collecting a standardized skin punch sample from the pelvic patch. We suggest calculating ≥ 80% of the distance between the caudal parts of the iliac crests of anuran, and matching this distance to the diameter of the cutting blade (Figs. 2, 3). For a clean cut that does not affect underlying tissues, raise the skin at any point on the circumference of the cut, preferably with forceps, to the iris of the punch apparatus. The next step is to separate the tissue from the few remaining points of attachment between the skin and underlying muscle; curved iris scissors are effective for this step. In this way, only the skin layer is sampled, leaving the muscle intact (Fig. 3). We suggest cutting a midline incision with a sharp blade in one clean cut. After this, the sample can be readily fixed and preserved in 10% buffered formalin, and later, histopathological standard protocols may be used to stain sections (4–6 µm thick) with hematoxylin-eosin (H & E) (Berger et al. 1998; Berger et al. 2000), or any other relevant staining technique. Embedding the two skin segments together in paraffin and perpendicular to the microtome facilitates their subsequent sectioning (Fig. 3C).We suggest making 15 different cuts in each direction, starting from the middle to the sides and leaving a gap of at least 50 µm between each cut.

It is important to take certain precautions when conducting the biopsy: 1) if too much pressure is applied, you can cut the abdominal muscles or even fracture the ilium and urostyle (Fig. 2); 2) in a very large animal, you can make several cuts to cover the desired area; 3) we found that this technique should not be used on specimens with a snout–vent length < 2 cm as the bones are too fragile; 4) depending on the embedding mold size, it is better to wrap the sample in filter paper to prevent losing it; 5) use a mold with mesh; 6) when embedded in paraffin, the cuts must be completely perpendicular.

Whereas histopathology has been used for diagnosis of *Bd* infection in amphibians, it is not usually employed as a source of quantitative information. A small modification to the technique suggested by Berger et al. (2005) allows some useful standard quantification metrics. Once an infected section is identified, measure at least 2000 µm of continuous skin, and from that subsection, quantify the number of *Bd* sporangia, skin thickness, number of cell layers, or number of glands.

Although Cheng et al. (2011) have developed a technique to detect the presence of *Bd* in museum specimens by qPCR, this technique does not provide any other information, such as localized changes in tissues, or other changes that could indicate the actual disease status of the individual sampled. Histopathology is the only approach that allows us to identify skin lesions, such as hyperkeratosis, epidermal cell hyperplasia or atrophy, erosion, ulceration, and vascular and inflammatory changes, all of which are often indicative of a disease state rather than merely an infected state. We could combine both techniques, qPCR and histopathology, yet by histopathology alone we can detect both *Bd* infection and associated physiological symptoms of the disease chytridiomycosis. Our approach offers minimal destructive sampling, with potential standardization to facilitate comparisons among samples.

Acknowledgments.—We thank Laura Alvarado for suggestions and technical support with Histopathology Laboratory at the Escuela de Medicina Veterinaria, Steven Whitfield and Robert Puschendorf for providing helpful comments on an earlier draft of the manuscript, and Gerardo Alcides Sánchez Monge for the illustrations. Occurrence of *Batrachochytrium dendrobatidis* in Wapanocca National Wildlife Refuge, Arkansas, USA

The amphibian chytrid fungus, *Batrachochytrium dendrobatidis* (*Bd*) is known to have a wide distribution in North America (http://www.bd-maps.net/), but confirmed infections in areas of the American Mid-South are lacking. We surveyed an ephemeral water body in Wapanocca National Wildlife Refuge (WNWR), Turrell, Arkansas, USA. While other surveys have confirmed the presence of *Bd* in Arkansas via histology (Rothermel et al. 2008), no survey thus far has confirmed infections via the more-quantitative real time polymerase chain reaction (qPCR) method (Kerby 2012). Our survey was the first to quantitatively assess *Bd* presence on amphibians and their infection intensities in Arkansas.

On 20 May 2013, we surveyed Pecan Ridge ephemeral depression (35.331133°N, 90.221467°W) within WNWR (Fig. 1). With the assistance of the Ecological Census Techniques class from Christian Brothers University (CBU), we captured amphibians in this area with dipnets, water seines, and by hand. To sample for *Bd*, animals were swabbed using sterile cotton-tipped applicators (Fisherbrand®, Cat. #23-400-116), approximately 30 times along keratinized tissues (ventral surface and hind limbs) where *Bd* zoospores are concentrated (Marantelli et al. 2004). The swabs were placed in 1.5-mL snap-cap tubes (Fisherbrand®, Cat. # 02-681-272) and stored in a -18°C freezer until qPCR analysis was conducted to quantify *Bd* loads and prevalence. To minimize cross-contaminating animals and ensure that our results were accurate, gloves and equipment that contacted frogs were sterilized with 70% ethanol and dried between handling of individuals and all other equipment was sterilized with a 10% bleach solution or discarded after leaving each water body (Johnson et al. 2003).

Infection status (*Bd*+/-) of all animals was confirmed using qPCR following a method by Kerby et al. (2012). DNA was extracted from cotton swabs using Qiagen DNeasy Blood and Tissue Kit (Cat. #69506), and the extracted DNA was used in the qPCR reaction. Standards for the reaction were obtained from Commonwealth Scientific and Industrial Research Organisation laboratories, Australia, and were the same as those used in Boyle et al. (2004). The standards served as the positive controls (versus internal controls, Kerby et al. 2012) and each plate contained a negative control (which tested negative on all plates) and all samples were run in triplicate. For determination of infection status, swabs were categorized as *Bd*-positive when zoospore equivalents were ≥1 (as used by Vredenburg et al. 2010).

We captured and swabbed 46 adult Cricket Frogs (*Acris crepitans*). We detected *Bd* in 42 of 46 (87%) animals. In infected individuals, zoospore loads ranged from ~2 to >200,000 (it must be noted that the highest standard used in our experiment is 100 zoospore equivalents). No frog showed clinical signs of *Bd* infection (e.g., lethargy, skin sloughing), indicating that Cricket Frogs may persist in populations without succumbing to *Bd*-induced mortality (but see Rothermal et al. 2008). Our data is the first to show the presence of *Bd* in Arkansas when confirmed through

qPCR (Rothermel et al. 2008). Moreover, our survey is only the third to be conducted in Arkansas (www.bd-maps.net). Because *Bd* can only be detected from laboratory analyses of environmental samples, these efforts are warranted to help us understand its occurrence and risk to native populations, and address the spread of this potentially deadly disease.

Detection of *Batrachochytrium dendrobatidis* Infections in Amphibian Populations at Edward J. Meeman Biological Field Station, Tennessee, USA

Within North America, *Batrachochytrium dendrobatidis* (*Bd*) infections have primarily been reported in the western and northeastern parts of the United States (http://www.bd-maps.net/, Olson et al. 2013). Infections in other parts of the country (e.g., Tennessee) are currently recorded at a much lower incidence and so further survey data are needed to inform scientists and managers of *Bd* occurrences and risks to native fauna. Chatfield et al. (2009) confirmed *Bd* infections in the Great Smoky Mountains of Tennessee and Davis et al. (2012) confirmed *Bd* infections in Shelby County, Tennessee. Both of these studies confirmed *Bd* infection status via quantitative real time polymerase chain reaction (qPCR), the accepted standard in the field. However, *Bd* also was detected in Meeman-Shelby State Park, Tennessee (Venesky and Brem 2008), but unlike the other surveys in Tennessee, infection was only confirmed in a single individual via histology. To better understand the distribution of *Bd* in areas near Meeman-Shelby State Park, we surveyed ponds and lowlands adjacent to Meeman-Shelby State Park, specifically within the University of Memphis, Edward J. Meeman Biological Field Station (MBFS, 35.366667°N, 90.016667°W, Fig. 1).

On 8 May and 31 May 2013, we captured adult amphibians for *Bd* sampling at four sites within MBFS using dipnets, water seines, and by hand capture. Captures on 8 May were taken to the laboratory at the University of Memphis, Memphis, Tennessee for other projects and thus were not released back into the wild. This ensured that we did not recapture and resample amphibians.

To sample *Bd*, animals were swabbed using sterile cotton-tipped applicators (Fisherbrand, Cat. #23-400-116), approximately 30 times along the ventral surface and hind limbs (areas

TABLE 1. Results of *Batrachochytrium dendrobatidis* (*Bd*) sampling in adult anurans in Meeman-Shelby State Park, Tennessee, USA. Average zoospore loads (Avg. Zoo. Loads) indicate average *Bd* infection intensities in infected individuals.

Site Location	Date Collected	Species	No. *Bd* +/ No. Sampled	Avg. Zoo. Loads
Levee Pond 35.354831°N, 90.011003°W	08 May 2013	*Lithobates clamitans*	1/1	31.13
The Ditches 35360761°N, 90.01295°W	08 May 2013	*Acris crepitans*	13/14	1231.21
		Lithobates sphenocephalus	5/5	4484.84
Cattle Tank Array 35.362997°N, 90.016981°W	31 May 2013	*Hyla versicolor/ chrysoscelis*	0/27	NA
Student Dorm 35.360433°N, 90.018261°W	08 May 2013	*Scaphiopus holbrookii*	0/2	NA
		Anaxyrus fowleri	0/3	NA

of keratinized tissues) where *Bd* zoospores are concentrated (Marantelli et al. 2004). We captured and swabbed 52 amphibians from 6 species (Table 1). The swabs were placed in 1.5-mL snap-cap tubes (Fisherbrand®, Cat. #02-681-272) and were stored at -18°C until qPCR analysis to quantify *Bd* presence and intensity. To minimize cross-contaminating animals, gloves and equipment that contacted frogs were sterilized with 70% ethanol and dried between handling of individuals, and all other equipment was sterilized with a 10% bleach solution or discarded after leaving a pond (Johnson et al. 2003).

Infection status (*Bd*+/-) of all animals was confirmed using qPCR following the method used by Boyle et al. (2004). DNA was extracted from cotton swabs, and the extracted DNA was used in the qPCR reaction. Standards for the reaction were obtained from Commonwealth Scientific and Industrial Research Organisation labs in Australia and were the same as those used in Boyle et al. (2004). The standards served as the positive controls (versus internal controls, Kerby et al. 2012) and each plate contained a negative control (which tested negative on all plates) and all samples were run in triplicate. We used the same "fast" qPCR technique detailed and proven successful by Kerby et al. (2012). For calculations of prevalence, swabs will be categorized as *Bd*-positive when zoospore equivalents were ≥1 (as used by Vredenburg et al. 2010).

Overall, 19 of 52 (37%) individuals tested positive for *Bd* (Table 1). In infected individuals, zoospore loads ranged from ~28 to >500,000. Only three of six species sampled (Cricket Frogs [*Acris crepitans*], Green Frogs [*Lithobates clamitans*], Southern Leopard Frogs [*Lithobates sphenocephalus*]), tested positive for *Bd*. These species have been found infected previously in the wild (Rothermel et al. 2008). The other three species sampled (Fowler's Toads [*Anaxyrus fowleri*], Gray Treefrogs [*Hyla versicolor/chrysoscelis*], and Spadefoot Toads [*Scaphiopus holbrookii*]) tested negative for *Bd* infections, however our sample sizes were low such that if *Bd* occurred at a low frequency it may not have been detected. For example, Skerratt et al. (2008) recommended sample sizes of >59. *Bd* has previously been detected at low levels in both *A. fowleri* and *H. versicolor/chrysoscelis* populations (Davis et al. 2012; Rothermel et al. 2008), but other surveys also have shown a lack of infection in individuals of these species (Green and Dodd 2007; Longcore et al. 2007; Rothermel et al. 2008; Rodriguez et al. 2009).

The lack of infection in the individuals in our survey demonstrates that environment or some context of the population may play in role in susceptibility of *A. fowleri* and *H. versicolor/chrysoscelis* to *Bd*. Moreover, the lack of infection in *S. holbrookii*

FIG. 1. County map of Tennessee, USA. The Edward J. Meeman Biological Field Station is located in adjacent to Meeman-Shelby State Park (star within Shelby Co.).

corroborates previous surveys that also failed to confirm *Bd* infections in *S. holbrookii* populations (Daszak et al. 2005; Rollins et al. 2013); however, *S. holbrookii* have been experimentally infected in laboratory settings (Brem et al. 2013).

The observed differences in pathogen presence and intensity could also be explained by host immunity. Previous work has shown that amphibians vary in their susceptibility to *Bd*. For example, Gervasi et al. (2013) showed that members of the Ranidae family carried lower infection loads compared to those in Bufonidae and Hylidae. Alternatively, Searle et al. (2011) showed that *Bd*-induced mortality varied greatly, even within family. Such results illustrate the possibility for innate species-specific susceptibly to *Bd*.

Our data is the first to show the presence of *Bd* at MBFS when confirmed through qPCR. Moreover, our survey is only the fourth effort in the state of Tennessee (www.bd-maps.nets). Because *Bd* can only be detected from on-the-ground sampling efforts and laboratory analyses, such efforts to determine the distribution and spread of *Bd* are necessary to assess risk to species, especially considering the occurrence of *Bd* in areas where no documented amphibian declines have occurred.

Acknowledgments.—G. Burton and C. Vlautin assisted in the collection of amphibians. Funding was provided by Christian Brothers University Biology Department and the University of Memphis Department of Biological Sciences. Collection permits from

Meeman-Shelby State Park (#2010-004) were obtained prior to collecting the animals.

Spatial Pattern of *Batrachochytrium dendrobatidis* Infection in Green Frogs (*Lithobates clamitans*) in Michigan, USA

Catastrophic amphibian declines occurring in tropical areas as a result of the growth and spread of the pathogenic fungus *Batrachochytrium dendrobatidis* (*Bd*) are well documented (e.g., Berger et al. 1998; Lips et al. 2006, 2008; Skerratt et al. 2007; Wake and Vredenburg 2008), but impacts to temperate zone species remains less well known. The Bd Mapping Group has been synthesizing existing data (Olson et al. 2013) to track the occurrence of *Bd* from all locations from where it has been tested, but data are lacking for many areas and species. Understanding the role of environmental variables in the growth or spread of *Bd* may provide local guidance to inform management efforts to address amphibian populations at risk. Several factors likely affect the establishment and growth of the fungus in different amphibian populations, including temperature. Both an optimal temperature (23°C) for *Bd* growth and a temperature at which growth is inhibited (29°C) has been indicated (Longcore et al. 1999, Piotrowski et al. 2004). Recently, temperature range at a site has been correlated with the odds of *Bd* occurrence at global- and USA-spatial scales (Olson et al. 2013) and can be influenced by environmental disturbance (Becker and Zamudio 2011; Becker et al. 2012). Occurrence of *Bd* is also thought to be correlated with latitude (Kriger et al. 2007) perhaps as a proxy for temperature and/or precipitation. Additional data are required to determine if a local-regional relationship can be established between *Bd* infection patterns and other factors such as latitude.

Very little is known regarding the occurrence of *Bd* within Michigan amphibians nor the factors most important to impacting their susceptibility to *Bd* infection. One study predicted the

occurrence of *Bd* in Michigan (Ron 2005) and *Bd* has been reported for two Michigan species (*Lithobates sylvaticus* [= *Rana sylvatica*]: Zellmer et al. 2008; *Acris crepitans blanchardi*: Steiner and Lehtinen 2008). However, few individuals and populations were surveyed, and only in southern Michigan.

Our study examined the influence of environmental factors on the prevalence of *Bd* infection in Michigan, USA populations of Green Frogs (*Lithobates clamitans*). This frog is a habitat generalist, its range spans the entire state, and it is typically easy to locate. *Lithobates clamitans* has been documented as a carrier of the fungus in other studies and has exhibited a common infection prevalence of ~20% across several studies (Ouellet et al. 2005). Hence this species is well suited for a study determining whether specific environmental factors, unrelated to the identity of the host species, have an effect on *Bd* infectivity and/or prevalence patterns. By using an organism with a wide geographic range, high prevalence as a resistant carrier, and general habitat preferences, a broad range of environmental variables can be tested and compared, eliminating a host effect which is created when using several different host species to evaluate environmental variables. Our study objectives were to survey for the presence of *Bd* in *L. clamitans* throughout Michigan, and examine whether the prevalence of *Bd* infection is influenced by specific environmental conditions. Simultaneously, we investigated the relationship of pH, temperature, conductivity of the water, and latitude with the prevalence and infection load of *Bd*.

Thirty-three sites in Michigan were sampled between 19 May and 20 September 2009 (Fig. 1; Appendix A). Without prior knowledge of *Bd* occurrence, sites were chosen based on the likely occupancy of *L. clamitans*, the spread of sites with respect to latitude, and accessibility. Most sites were permanent bodies of water ranging in size from small ponds (89 m^2) to large lakes (1214 ha).

Several environmental variables were measured at each site while simultaneously collecting *Bd* samples: water temperature (°C), conductivity (µMhos), pH, humidity, air temperature (°C), and elevation (m). Water temperature and conductivity were collected using a YSI (Yellow Springs Instrument Co. Inc., Yellow Springs, Ohio, USA) Model 33 S-C-T meter with a 3310 probe. The pH data was collected using a Double Junction pHTestr10 (Oakton instruments, Vernon Hills, Illinois, USA). Air temperature and humidity were recorded from the NOAA weather website (www.noaa.gov). Elevation was determined from a GeoPositioning System, TOPO! version 3.4.0 (National Geographic Holdings, Evergreen, Colorado, USA).

The shorelines of the ponds and lakes were surveyed for the presence of *L. clamitans* from 19 May to 20 September 2009 working from southern localities to northern localities as weather permitted and frog activity increased. Frogs were captured using gloved hands or nets. Equipment and vinyl gloves were changed after each capture to avoid cross contamination between specimens. Each frog was kept alive in a plastic bag until it could be sampled. To avoid resampling the same individuals, we continued surveying and capturing approximately 5 m away from the release point, in a direction away from the previous captures. Sampling was considered complete if the entire shoreline had been covered, or more than 35 frogs had been captured. Once sampling at a site was completed, all gear (boots, waders, etc.) was disinfected with a dilute (10^{-1}) bleach solution to avoid cross contamination of sites.

Each frog was swabbed with a sterile Medical Wire MW113 cotton-tipped, plastic shaft swab (Medical Wire & Equipment Co. Ltd., Corsham, Wiltshire, UK). The swab was rubbed in one direction five times on the ventral surface of the body, between the forelimb and hindlimb on each side of the body, on the ventral surface of each thigh, and once between each toe on the ventral surface of the webbing. The swab was then placed in a 1.5 ml centrifuge tube with the screw cap left open to let the swab air dry. Once the swab was dry, the tube was capped and stored at

4°C until it could be processed. Frogs were identified as male, female, or immature (too young to confidently sex). Each frog was weighed to the nearest 0.5 g using a Pesola spring scale (Pesola Scales, Kapuskasing, Ontario, Canada). Snout-vent length (mm) was measured to the nearest 1.0 mm using SPi 2000 dial calipers (Swiss Precision Instruments, Inc., Garden Grove, California, USA). Any abnormalities were also noted, including abrasions, lesions, discoloration, and deformities. Equipment was disinfected with a dilute bleach solution after each use.

To extract DNA, 40 µl of PrepMan Ultra Sample Preparation Reagent was added to the 1.5 ml centrifuge tube containing the swab. The tube was heated to 100°C for 10 min and then allowed to cool for at least 2 min. After cooling, the tube was centrifuged for 3 min at 13,000 rpm, then a minimum of 20 µl of supernatant was transferred to a 200 µl PCR tube. Five µl of the supernatant was diluted 10^{-1} in 0.25xTE buffer (pH 7.6). The diluted samples were then stored at -20°C until they could be analyzed using a validated quantitative real-time PCR (qPCR) assay (Boyle et al. 2004; Hyatt et al. 2007). The primers and minor groove binding (MGB) probe used in the qPCR assay were the same *Bd* DNA specific sequences used in Boyle et al. (2004).

An ABI 7500 Real-Time PCR System (Applied Biosystems, Inc., Foster City, California, USA) was used for the qPCR assay. Conditions for qPCR analysis were as follows: 2 min at 50°C, 10 min at 95°C, and 50 cycles of 15 s at 95°C, 1 min at 60°C. Each 96-well plate contained 4 standards at known zoospore concentrations of *B. dendrobatidis*, 1 negative control without DNA template, and 27 unknown samples in triplicate (triplicate = 3 aliquots from each swab sample extraction). Known DNA concentrations, provided by the Australian Animal Health Laboratory, were used to create 100, 10, 1, and 0.1 zoospore equivalent (zsp) standards. The known concentrations were then used to create a standard curve for each qPCR assay performed. Reaction volumes were 25 µl and contained 1X Taqman Environmental

TABLE 2. Results of a stepwise regression using Log prevalence of *Batrachochytrium dendrobatidis* infections in *Lithobates clamitans* at 29 infected sites in Michigan, USA, in 2009 as the dependent variable and 5 independent predictor variables. A backward elimination with an α of 0.1 was used to remove predictor variables.

Master Mix 2.0 (Applied Biosystems, Inc., Foster City, California), 900 nM concentration of each primer, 250 nM concentration of the MGB probe, and 5 µl of DNA template.

An individual frog sample was considered positive if at least one of the triplicate swab samples amplified during the qPCR assay. It was not uncommon for only 1 or 2 replicates to amplify, especially if the quantity was low. The actual quantity of zoospore equivalents for each sample was acquired by comparing critical threshold (Ct) values (the cycle in which a sample has amplified past a set threshold) of unknown samples to the Ct values of the standard curve. The quantity for each sample represented a mean of the PCR analysis of the swab sample, if more than one replicate was positive. The prevalence of positive individuals at each site was calculated by taking the number of positive frogs and dividing that number by the number of frogs sampled. The zsp mean of each site was calculated by taking an average of only the infected individuals from that site.

A correlation between average infection load (log transformed) and site prevalence (log transformed) was performed in Minitab 14 (Minitab Inc., State College, Pennsylvania, USA). Prevalence data was log transformed and tested for normality before and after transformation. To check for colinearity between the independent variables, a correlation matrix analysis was performed prior to the stepwise regression in Minitab 14 and one of two variables with a strong correlation (Pearson correlation value above 0.7) was selected. A stepwise regression was performed in Minitab 14 using the prevalence of positive individuals at a site as the dependent variable and several possible explanatory factors: water temperature (°C), conductivity (µMhos), pH, latitude, and elevation. A backward elimination was used to remove independent variables using an of 0.1 as a threshold. Logistic regression was performed in Minitab 14 using positive or negative infection of an individual as the dependent variable, and mass (g) and sex of the frog as the independent variables. Sex of the frog actually included three categories: male, female, and immature (too young to reasonably determine sex). The quantity of zoospore equivalents data was log transformed and tested for normality before and after transformation. Anderson-Darling test for normality was used for all normality tests using Minitab 14.

We found that *Bd* is widespread in Michigan, being detected on 160 of 477 (35%) *L. clamitans* sampled (Table 1). Only 4 of 33 sites visited were *Bd*-negative. Infected individuals ranged in their infection load from 0.08 to 2,176 zoospores. The site average infection load (log transformed) and site prevalence (log transformed) were positively correlated ($r_{27} = 0.783$, $p < 0.001$; Fig. 2).

Latitude was associated with *Bd* prevalence ($T_{23} = -4.15$, $p < 0.001$; Fig. 3) and explained a significant proportion of the

variance in prevalence between sites ($F_{5,28}$ = -0.102, r^2 = 38.94, p < 0.001; Table 2). Most independent variables were not strongly correlated with each other (Table 3), however, latitude and water temperature had a significant relationship (r_{27} = 0.527; p = 0.002).

The relationship between latitude and *Bd* prevalence was significant when analyzing only the *Bd*-positive animals, so that a subset of sites were included in this analysis. Given that prevalence was 0.335 for all sites combined (160/477 individuals from all sites), 8 individuals would need to be sampled in order to be 96% confident that a site was *Bd*-free, and 12 individuals would need to be sampled to be more than 99% confident that a site was *Bd*-free. Since not enough individuals were collected at sites with 0% prevalence to confidently assume absence of the fungus, they were excluded from this analysis. According to the Anderson-Darling test value (AD) for the site prevalence data, the data was not normal before log transformation (mean = 0.4548, SD = 0.2774, AD = 1.327, p = <0.005). After log transformation, the data was normal (mean = -0.4233, SD = 0.2805, AD = 0.453, p = 0.253).

There was no relationship between an individual frog being infected or not (N = 449) and either mass (g) (z_1 = 0.43, p= 0.665) or sex (χ^2_2 = 0.679,p= 0.712), or both (G_3 = 0.686,p= 0.877). There was no difference in the number of zoospores infecting female and male *L. clamitans* (T_{111} = -0.649056, p = 0.518; Fig. 4). According to the Anderson-Darling test value for the zoospore quantity data for females and males, the data was not normal before log transformation (female: mean = 17.65, SD = 26.31, AD = 6.27, p = <0.005; male:mean = 65.13, SD = 283.7, AD = 20.953, p = <0.005). After log transformation female data was normal, but the male data was not (female: mean = 0.923, SD = 0.522, AD = 0.386, p = 0.377; male:mean = 1.000, SD = 0.670, AD = 2.115, p = <0.005).

Our study indicates that *Bd* has a broad distribution on *L. clamitans* in Michigan, where frogs had a relatively low infection load. This is consistent with the findings of Ouellet et al. (2005) who found infected *L. clamitans* in areas surrounding Michigan and in bordering Canada, as well as the findings for *L. sylvaticus* (Zellmer et al. 2008) and *Acris crepitans blanchardi* (Steiner and Lehtinen 2008) in Michigan. Among those sites where *Bd* was not detected, it was impossible to infer absence due to low sample sizes. Low sample sizes may have resulted from few frogs at a site or low detectability of frogs (e.g., if dense shoreline vegetation made it difficult to catch more than a few frogs). Although there was no obvious reason for some sites to have only a few *L. clamitans* inhabiting them, one possibility is that sites with few individuals could have been subject to a recent *Bd* die-off, with only a few *Bd*-resistant individuals remaining (or perhaps new individuals are colonizing and repopulating). Elsewhere, the species was thought to have been extirpated at sites, possibly due to *Bd*, and have now been rediscovered (Rodriguez-Contreras et al. 2008). Without ongoing monitoring over a long period of time it is not possible to detect such a die-off or recovery event.

One factor, latitude, was associated with *Bd* infection prevalence. As latitude increased, *Bd* infection decreased at our Michigan sites. Our samples at the highest latitudes were somewhat clumped in the Upper Peninsula (UP), but with all UP samples removed the significant relationship was still present at a $p < 0.1$ level (r_{20} = 0.319; p = 0.085). We also examined the relationship when adding in only single UP samples and the relationship was present at much lower p values (p values ranged from 0.05 to 0.003). Latitudinal variation was linked to *Bd* infection prevalence and intensity in other studies (Kriger et al. 2007; Rödder et al. 2008). Kriger et al. (2007) found that a significant relationship between *Bd* infection intensity and latitude was likely due to changes in precipitation along a large-scale latitudinal gradient (15–40°S) in Australia. The latitudinal gradient explored in our study was at a much smaller scale, between 42–47°N. A significant relationship at such a small scale is interesting and deserves further exploration to determine the exact cause of this relationship. Latitude is likely a proxy for one or more environmental factors not explored in this study that influences infection rates at Michigan sites.

Temperature associations with *Bd* infection have been documented (Becker and Zamudio 2011; Becker et al. 2012; Longcore et al. 1999; Andre et al. 2008; Olson et al. 2013). The fungus is known to grow best in a limited range of temperatures (Longcore et al. 1999; Piotrowski et al. 2004) and prevalence and severity of *Bd* has been reported to vary seasonally (e.g., Berger et al. 2004; Kriger et al. 2007). One Michigan study (Zellmer et al. 2008) found support for seasonality in Michigan *L. sylvaticus* but very small samples sizes in only a few, southern localities were sampled and this species is much more terrestrial than is *L. clamitans*. In our study, water temperature at the time a sample was taken did not correlate with infection results. However, it is possible that another temperature variable could be influencing *Bd* infection. One temperature variable that changes with latitude is average yearly temperature at a site. Sites further north have a lower average yearly temperature than sites in southern Michigan, but also a greater range in temperatures. This provides a possible explanation for the decrease in *Bd* prevalence at higher latitudes. It may be that the greater range in temperatures, as well as the lower annual average temperature, allows for *Bd* to grow and persist but not to reach high levels of infection as found in other areas. That remains to be investigated and managers should be aware that the more pristine areas of northern Michigan might be at greater risk for amphibian *Bd* infections.

Acknowledgments.—We thank the Michigan Department of Natural Resources, Portage City Parks, and Au Sable Institute of Environmental Studies for permitting access to sites. Funding for this project was provided by John Ball Zoological Wildlife Fund, West Michigan Chapter of the American Association of Zookeepers, and Huron Mountain Wildlife Foundation (HMWF). The authors complied with all applicable institutional Animal Care guidelines (CMU IACUC #09-10 and 09-11) and all required State and Federal permits were obtained. We also gratefully acknowledge valuable editorial comments and assistance from Jeremy J. Gibson-Brown, Karen Lips, A. Scott McNaught, and Bradley J. Swanson. We also would like to thank Christopher Morabito, Mary Mattson, Victoria Mukans, and Megan Trujillo for assistance in the field.

Assessment of *Batrachochytrium dendrobatidis* Infection Level in Amphibians of Wakonda State Park, Missouri, USA

We determined the infection level of *Batrachochytrium dendrobatidis* (*Bd*) in the amphibian community of Wakonda State Park, Lewis Co., Missouri, USA, during the summer of 2010. Wakonda State Park consists of 420 ha of sand prairie, deciduous woodland, wetland, and wet prairie habitats, and 130 ha of wetland and deepwater habitats. There is little topographical relief with elevation ranging from 140 to 155 m above sea level (MODNR 2007).

We conducted two-person diurnal and noctural opportunistic surveys on seven different occasions in June and July 2010 and 17 September 2010. We surveyed 8 localities in the central (Cottonwood Pond, Quartz Lake, Agate Lake Road), southern (Main Park Road), northern (Sand Pit Lake, Buttonbush Slough, road to Jasper Lake), and western (Black Willow Marsh) regions of the park. We captured amphibians by hand using sterile technique (Livo 2004) and recorded species, capture date, and location. We swabbed amphibians following Livo (2004). We stored swabs in 70% EtOH solution and returned swabs to Truman State University for PCR analysis (Gaertner et al. 2009).

We captured and swabbed 39 individuals (17 *Lithobates catesbeianus*, 11 *Hyla versicolor*, 7 *Anaxyrus americanus*, and 4 *Acris crepitans*) during the study. Of those, zero individuals tested positive for *Bd*. The apparent lack of infection may be due to the warm, dry conditions, and large temperature range of Wakonda State Park, particularly during our sampling periods (Berger et al. 2004; Olson et al. 2013). Alternatively, *Bd* may occur within the park, but exist at low levels during inhospitable times of the year (Berger et al. 2004), and hence our low sample size may have precluded detection (Skerratt et al. 2008).

Although we cannot conclude that *Bd* is absent from the park, our data are an important first step in addressing potential infection levels here. A more thorough sampling of the amphibians of Wakonda State Park is warranted, taking into account seasonal variation in climatic conditions, to inform resource management decisions.

Acknowledgments.—The Missouri Department of Natural Resources provided funding for the project. All research was approved by a Missouri Department of Conservation permit to CEM and CL and a Missouri Department of Natural Resources permit to CEM. All research was conducted in accordance with Truman State University IACUC guidelines. We thank L. Wilbeck, J. Mantooth, and K. Scott for assistance in the field and logistical support. We thank E. Brochschmidt, M. Mueller, and J. Plaggenberg for assistance in the laboratory.

Prevalence of the Amphibian Chytrid Fungus (*Batrachochytrium dendrobatidis*) at Buenos Aires National Wildlife Refuge, Arizona, USA

Information on disease presence can be of use to natural resource managers, especially in areas supporting threatened and endangered species that occur coincidentally with species that are suspected vectors for disease. Ad hoc reports may be of limited utility (Muths et al. 2009), but a general sense of pathogen presence (or absence) can inform management directed at threatened and endangered species, especially in regions where disease is suspected to have caused population declines (Bradley et al. 2002). The Chiricahua Leopard Frog (*Lithobates chiricahuensis*), a species susceptible to infection by the amphibian chytrid fungus (*Batrachochytrium dendrobatidis*, *Bd*) (Bradley et al. 2002), and the non-native, invasive American Bullfrog (*L. catesbeianus*), a suspected vector for *Bd* (Schloegel et al. 2012; Gervasi et al. 2013), both occur at Buenos Aires National Wildlife Refuge (BANWR) and surrounding lands in southern Arizona, USA. Efforts to eradicate the bullfrog from BANWR began in 1997 (Suhre 2010). Eradication from the southern portion of BANWR was successful by 2008 but the bullfrog remains present at Arivaca Cienega and in areas immediately adjacent to the refuge (Fig. 1). Curtailing the re-invasion of the bullfrog into BANWR will require vigilance as to ensure the health of Chiricahua Leopard Frog populations. In conjunction with our regular occupancy surveys on BANWR, as part of the Amphibian Research and Monitoring Initiative, we added sampling for *Bd* to ranids and monsoon-breeding amphibians. The sampling was added to determine if *Bd* was present in Chiricahua Leopard Frog and American Bullfrog populations. We also wanted to determine if the monsoon-breeding amphibians were potential reservoirs for *Bd* since they will breed in pools that have ranids.

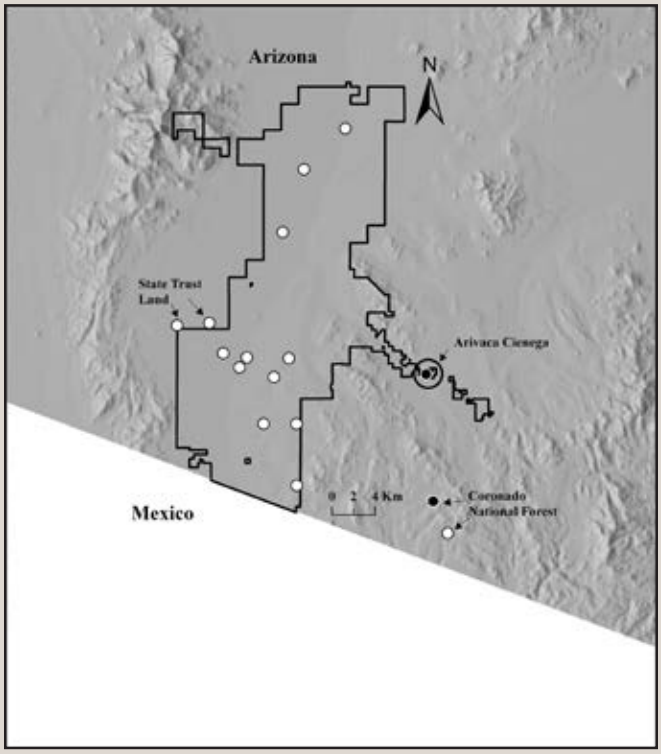

FIG. 1. Arizona, USA sampling locations: Buenos Aires National Wildlife Refuge (outlined), Coronado National Forest, and State Trust Land. Black circles indicate *Bd*-positive sites and white circles indicate *Bd*-negative sites.

In 2008, we collected external skin swab samples from 389 amphibians at BANWR (N = 11 sites), the adjacent State Trust Land (N = 2 sites), and the adjacent Coronado National Forest (N = 2 sites) (Table 1). Samples were collected by swabbing the dorsal, ventral, and feet of each amphibian using sterile swabs. The swabs were then placed in 95% ethanol and kept at or below 23°C. Distance between sites varied from 2 to 30 km. Sites for monsoon-breeding amphibians were selected opportunistically based on storm events and species occurrence. Ranid frogs (American Bullfrog, Chiricahua Leopard Frog) were sampled before the monsoon (June) at known sites; all other species were sampled during the monsoon (July to August). Swabs were tested for presence of *Bd* DNA using PCR (Annis et al. 2004) at the Human Origins Genotyping Laboratory, University of Arizona.

Across all samples, prevalence of *Bd* was low (0.02; Table 1). *Bd* was not detected on non-ranid frogs, perhaps because they are fairly terrestrial (Longcore et al. 2007). Among ranid frogs, *Bd* was not detected in the southern portion of BANWR. Only bullfrogs tested positive for *Bd* on the refuge, and those animals were from Arivaca Cienega (4/132, Table 1). Chiricahua Leopard Frogs tested positive for *Bd* at one site on the Coronado National Forest (6/25, Table 1). Our data parallel earlier reports on Chiricahua Leopard Frogs in Arizona, with *Bd*-positive reports for animals at other refuges around southern Arizona (San Bernadino National Wildlife Refuge, 2 individuals with characteristic lesions [Bradley et al. 2002]; Sycamore Canyon, Coronado National Forest, 1 individual tested positive via polymerase chain reaction (PCR) assay [Rosen and Caldwell 2004, www.bd-maps.net] but a negative result within the refuge [based on histological evaluation by D. E. Green, www.bd-maps.net]). Collectively, these results suggest that Chiricahua Leopard Frogs in Arizona are susceptible to infection by *Bd*.

TABLE 1. Nine amphibian species sampled for the occurrence of the amphibian chytrid fungus (*Batrachochytrium dendrobatidis*, *Bd*) in 16 water bodies on and adjacent to Buenos Aires National Wildlife Refuge, Arizona, USA. *Bd* prevalence and 95% confidence intervals shown.

Species	Common Name	No. Sampled	No. *Bd*-positive animals		*Bd* Prevalence (95% CI)
			On Refuge	Off Refuge	
Ambystoma mavortium	Western Tiger Salamander	26	1	0	0.00 (0.00–0.11)
Anaxyrus cognatus	Great Plains Toad	90	4	0	0.00 (0.00–0.03)
Gastrophryne olivacea	Western Narrow-mouthed Toad	9	1	0	0.00 (0.00–0.28)
Incilius alvarius	Sonoran Desert Toad	28	3	0	0.00 (0.00 –0.10)
Lithobates catesbeianus	American Bullfrog	142	1	2	0.03 (0.01–0.07)
Lithobates chiricahuensis	Chiricahua Leopard Frog	77	4	2	0.08 (0.03 –0.16)
Scaphiopus couchii	Couch's Spadefoot	8	4	0	0.00 (0.00–0.31)
Smilisca fodiens	Lowland Burrowing Treefrog	2	1	0	0.00 (0.00–0.78)
Spea multiplicata	Mexican Spadefoot	7	4	0	0.00 (0.00–0.35)

Prior to bullfrog eradication efforts, samples were collected from bullfrogs that had skin lesions or appeared unhealthy at a site 7 km from a Chiricahua Leopard Frog population at BANWR. Histological examination revealed *Bd* in 2 of 4 bullfrogs in 2003 and 3 of 7 bullfrogs in 2005 (D.E. Green, unpublished data). The absence of *Bd* on any species on the southern portion of BANWR in our recent assessment may be related to the absence of bullfrogs (Hossack et al. 2013; Longcore et al. 2007). This information should be useful to natural resource managers because extreme storm events causing extensive flooding (e.g., 2007: 30 cm of rain in July and August, 11 cm above average, Western Regional Climate Center, [http://www.wrcc.dri.edu/]) can facilitate dispersal of bullfrogs onto BANWR from outlying areas of the refuge, such as the Arivaca Cienega (Suhre 2010). Such re-invasion may facilitate the presence of *Bd* at ponds that support populations of ranid frogs at risk.

Acknowledgments.—We thank Buenos Aires National Wildlife Refuge for logistical support and C. Jarchow for assistance in the field. A special thanks to K. Ratzlaff and the Human Origins Genotyping Laboratory for processing the swabs. This is contribution number 445 of the U.S. Geological Survey Amphibian Research and Monitoring Initiative (ARMI). Use of trade, product, or firm names descriptive and does not imply endorsement by the U.S. Government.

HERPETOCULTURE

This section offers a publication outlet for manuscripts involving amphibians and reptiles in a captive environment—public or private. Subjects appropriate for this section include, but are not restricted to, the following:

- Novel techniques for maintenance and reproduction of live herpetofauna
- Genetic management of captive populations
- Legal issues in herpetoculture and animal trade: laws, regulations, permits
- Reviews of tools, equipment, technology, enclosures, etc.
- Safety protocols for working with dangerous species
- Policies and procedures related to preventing transmission of pathogens

Manuscripts that deal exclusively with veterinary medical subjects generally are not appropriate for this section, but consult Section Editor if in doubt.

Manuscripts, ideas, or questions should be directed to the Herpetological Husbandry Section Editors, Brad Lock (block@zooatlanta.org) or Wulf Schleip (wschleip@leiopython.de). All manuscripts will undergo external peer review. For detailed instructions on manuscript preparation, please consult the SSAR web page at: http://www.ssarherps.org/pages/HRinfo.php. When reporting on captive held animals, please also consider the *Guidelines for Use of Live Amphibians and Reptiles in Field Research*, accessible at: http://www.ssarherps.org/pages/HRinfo.php

For authors whose native language is not English and who might require assistance with manuscript preparation, we invite you to consult SSAR's Presubmission Manuscript Review service: http://www.ssarherps.org/page/presub.php.

In addition to conventional manuscripts, we will also publish brief notes based on limited observations of captive animals. These can be considered analogous to Natural History Notes and should be formatted the same way. Please consult that section for formatting guidelines. Subject matter examples include: breeding, courtship, clutch/litter size, gestation, growth, age at first reproduction, longevity, feeding preferences/techniques, thermal biology, unusual behaviors, and so forth. Contributions are welcome from all persons who work with captive amphibians and reptiles, including zoo biologists, private herpetoculturists, and institutional professionals.

Captive Management and Breeding of the Stuttering Frog (*Mixophyes balbus*) at Melbourne Zoo

The anuran genus *Mixophyes* consists of six species, five of which are restricted to moist forests of eastern Australia and one to the highlands of New Guinea (Donnellan et al. 1990; Tyler 1992; Tyler and Knight 2009). These moderately large terrestrial myobatrachids are commonly referred to as Barred Frogs due to varying degrees of barred markings on the hind legs. The Stuttering Frog, *Mixophyes balbus,* is restricted to the eastern slopes of the Great Dividing Range, from the Cann River catchment in far East Gippsland, Victoria; north to tributaries of the Timbarra River near Drake, northern New South Wales (NSW) (Gillespie and Hines 1999; Lemkert et al. 1997).

The species is typically found in the riparian zone of permanent streams, but may disperse into surrounding forests outside the breeding season (Daly 1998; B. Lewis, pers. comm.). Reproductive biology is similar to that of its congeners, particularly *M. fleayi* (Knowles et al. 1998). Oviposition has been recorded during the spring and summer months of October to February in shallow riffle zones in stream beds (Anstis 2002; Knowles et al. 1998; Lewis 2000; B. Lewis, pers. comm.). Eggs are laid in a shallow excavated nest, which the female forms by kicking the substrate outwards in a revolving motion (Knowles et al. 1998; Lewis 2000).

Mixophyes balbus has experienced a significant decline throughout its range (Gillespie and Hines 1999; Hunter and Gillespie 2011; Mahony 1996; Mahony et al. 1999; Tyler 1997). The southern portion of its range has experienced the greatest declines and the species may now be extinct in Victoria (Gillespie

Fig. 1. Breeding enclosure for *Mixophyes balbus* at Melbourne Zoo, with the areas of deep substrate and below-substrate drainage.

2011; Gillespie and Hines 1999). In NSW *M. balbus* is listed as Endangered under the Threatened Species Conservation Act, 1995. In Victoria it is registered as Threatened in the Victorian Flora and Fauna Guarantee Act of 1988 and listed as Critically Endangered in the Advisory List of Threatened Vertebrate Fauna in Victoria 2012 (DSE 2012). Nationally, *M. balbus* is listed as Vulnerable under the Environment Protection and Biodiversity Conservation Act 1999. Globally it is listed as Vulnerable (C1 and 2a (i)) by the IUCN (2012).

A recent genetic study identified two major lineages within what is currently known as *M. balbus*, with an overlap zone in the vicinity of the Barrington Tops region, NSW (Donnellan 2008; M. Mahony, pers. comm.). The level of genetic divergence between these two lineages, hereafter referred to as clades, is greater than that recorded among other *Mixophyes* species, suggesting that more than one taxon currently exists within *M. balbus* (Donnellan 2008). This issue is reflected in the National Recovery Plan for the Stuttering Frog, which recommends that, until this taxonomic issue is resolved, the two lineages of the Stuttering Frog "should be given the highest level of conservation priority and managed independently" (Hunter and Gillespie 2011).

Increased interest in the conservation of native Australian frogs resulted in frogs in the genus *Mixophyes* being identified as a priority taxon for regional management by Australasian zoos in 1996 (Banks 1993; Banks and Meikle 1994; Gillespie et al. 2007). Melbourne Zoo took the lead in this initiative, initially focusing on the Great Barred Frog, *Mixophyes fasciolatus*, to develop the necessary husbandry expertise as an analogue for working with more threatened species in this genus. Commencing in 1993, the husbandry and breeding of *M. fasciolatus* proved straightforward (Banks et al. 2003).

Melbourne Zoo has since maintained and bred both clades of *M. balbus*. The founding sample of the northern clade *M. balbus* was collected as adult frogs in February 2001 at Duncan's Creek in the Malara State Forest on the Timbarra Plateau, north-east NSW, within the boundaries of the Timbarra Gold Project (Mining leases 1386 and 1426), and consisted of 4 males, 3 females, and 20 tadpoles. None of the tadpoles survived the transfer to Melbourne Zoo, despite the containers being buffered from sudden movements and the tadpoles having adequate volumes of water and in-container vegetation. The container was aerated and we believe that the water circulation created too much turbulence for the tadpoles. Post-mortem examination did not reveal a cause of death.

Individuals of the southern clade *M. balbus* were collected as tadpoles in Macquarie Pass National Park, southern NSW, in January 2005. Twenty tadpoles were collected, 10 transferred to Melbourne Zoo and 10 to the Amphibian Research Centre (ARC), in outer Melbourne.

Captive Management

All life stages of both clades of *M. balbus* were maintained under the same conditions at Melbourne Zoo, except where otherwise indicated.

Maintenance of adult frogs: Northern clade.— Adult frogs were maintained in glass aquaria in two groups, group one consisted of 2.1 (two males: one female) and group two of 2.2. These two groups were combined in one group of 3.3 frogs in July 2002, one male having died soon after arrival. Frogs were maintained under Melbourne Zoo amphibian quarantine protocols (Lynch 2001). Each enclosure measured 1800 × 450 × 450 mm tall and was designed to simulate a cross-section of a flowing stream (Fig. 1). Two areas of deep substrate, at each end of the enclosures, were provided to allow for burrowing. The substrate consisted of 50 mm of leaf litter over 250 mm of palm peat, on top of a 50 mm layer of aquarium gravel on fiberglass fly mesh, supported approximately 50 mm above the base to allow drainage. Each deep substrate area contained one permanently plumbed drainage hole of 25 mm diameter. The substrate was regularly flushed and the palm peat was occasionally turned to assist with aeration and reduce compaction.

Water was supplied between the two deep substrate areas. An aquarium power-head pumped the water from a wet trickle filter located below the enclosure on to rocks within the water body. This created a small splash zone; the water then flowed through a simulated riverbed and overflowed back to the filter. A second pump, also located in the filter, pumped water through a spray bar located on top of the enclosure to simulate rain. The rain simulation pump was operated sporadically, coinciding with low-pressure systems and rain events as they occurred in the local (Melbourne, Victoria) area. The riverbed consisted of 10–150 mm river stones, which created pools varying in depth from 5–250 mm. Shallow riffle zones were created using 5 mm aquarium gravel mixed with coarse river sand. Logs and larger rocks were placed along the water's edge to create sheltering sites and locations for males to call from.

From February 2001 until July 2002 the tanks were located beside each other within an off-limit holding area in Melbourne Zoo's Reptile House. Ambient air temperature was 17–23°C during winter and 23–28°C during summer. After July 2002 both enclosures were maintained in an air-conditioned room adjacent to the World of Frogs facility, with an ambient air temperature of 9–16°C during winter and 17–25°C during summer. A large vent in an external door was opened during winter to allow the ambient temperature to drop below the minimum achievable by the air conditioner. Exposure to Melbourne's natural annual photoperiod of 9.5 h daylight during winter and 14.75 h during summer was provided via skylights and windows. Commencing in 2008, all frogs also had two Repistar® 18-watt globes installed above each aquarium, providing UVA and UVB radiation.

TABLE 1. Spawn date, egg and breeding female data for northern clade *Mixophyes balbus* at Melbourne Zoo.

Spawn date	Number of eggs laid	Nest length x width x depth (mm)	Female weight pre-oviposition (g)	Female weight post-oviposition (g)	Water temperature Av. (min/max)°C	Days until hatching commenced	Days until hatching finished	Percent fertile
13.02.01	120	50 x 50 x 20	48.5	35.6	25.5 (21–27)	6	8	95%
15.02.01	140	58 x 58 x 20	55.5	49	25.5 (21–27)	6	8	90%
19.02.01	130	58 x 58 x 20	49	43.3	25.5 (21–27)	6	8	95%
30.05.01	210	55 x 55 x 25	56	46.4	20 (17–22)	8	10	80%
2.09.04	280	50 x 80 x 20	49.2	45.2	18 (15–22)	10	14	95%
5.09.04	310	65 x 65 x 25	56	49.1	18 (15–22)	10	14	85%
9.09.04 (*)	140	50 x 45 x 18	N/R	N/R	18 (15–22)	10	14	20%
6.04.06	532 (**)	N/R	N/R	N/R	18 (15–22)	Eggs not retained	–	–

N/R – not recorded.
(*) – F2 breeding; frogs from spawn laid 30 May 2001.
(**) – possibly more than one spawning.

For the 2004 breeding season a glass aquarium measuring 800 × 750 × 500 mm tall was used specifically for breeding. This simulated a natural riffle zone and was without a deep substrate area. The river area was set up as described for the previous enclosure, although it was slightly larger and hence provided more potential spawning sites for the female frogs. A second pump was used to circulate water through a spray bar to simulate rain throughout the enclosure. The rain simulation pump was operated by a timer and programmed to operate for 15 minutes every hour.

Each frog was implanted with a passive integrated transponder (PIT) in the left inguinal pocket for identification and sex was determined by size. Adult females measured 76–77 mm SVL and males 55–57 mm SVL. Calling males also had well-developed nuptial pads and darker yellow throats and bellies, compared to the white/grey of the females.

Southern clade.—Southern clade frogs were maintained in the conditions detailed above, but in one all-glass aquarium at a sex ratio of 3.2.1 (3 males: 2 females: 1 adult of undetermined sex). This had a recirculation filter and single pump, and the substrate was removed and replaced with fresh materials annually. These frogs were kept in the off-limit section of the World of Frogs at an ambient temperature of 9–16°C during winter and 17–25°C in summer.

Due to their smaller size, only one southern clade frog was micro-chipped. Photographs of dorsal patterns were used to identify all other frogs.

Feeding

Frogs were fed weekly during winter and twice weekly during summer. Food was predominantly commercially available crickets, although locusts were also provided occasionally for variety. One wild-collected adult male northern frog died after eating a large locust approximately twice the width of the frog's head. Gross necropsy and pathology suggested the gut was perforated by the locust's hind leg. Subsequently, locusts no larger than the width of the frog's head were offered. Calcium carbonate or multivitamin powder was dusted on all insects prior to feeding.

Maintenance of Tadpoles

Tadpoles of both clades were reared in all-glass aquaria 450 × 530 × 150 mm deep containing 19 L of water, and 400 × 750 × 180 mm deep containing 50 L. Tadpole tanks had overflow pipes, each with a grill cover to prevent tadpoles from being accidentally flushed down the drain. Water quality was maintained by dripping a constant supply of fresh water into the tank at approximately 2.0 L per hour. Rate of flow was increased or decreased according to stocking density and water quality. Each tank had an aquarium air stone for oxygenation and to aid water movement. No substrate or other internal furnishings were provided.

Water quality was measured using a Master Test Kit® and a Nitrate Test. Municipal tap water was aged in a large 800 L tank for approximately 24 h prior to being used. Once aged, the general water parameters were pH = 6.9, general hardness (GH) = 17.9 ppm, carbonate hardness (KH) = 17.9 ppm, ammonia (NH_3/NH_4+) = 0 ppm, nitrite (NO_2^-) = 0 ppm, and nitrate (NO_3) = 0 ppm. These parameters were similar to water tested from the tadpole collection site (Duncan's Creek tributary, Timbarra Plateau). Water quality in the aquaria was maintained at the same parameters except for nitrate, which varied between 0–5.0 ppm.

Tadpoles were fed a varied diet of frozen (and then thawed) endive 7 times weekly and Saga® tropical fish flakes weekly. Spirulina Pro® was fed *ad libitum*, approximately once every 7–10 days. Once tadpoles reached Gosner Stage 26 (hind limb buds, Gosner 1960), protein was increased by adding either frozen bloodworms or frozen brine shrimp every second day.

Maintenance of Metamorphs and Juvenile Frogs

Newly metamorphosed frogs were maintained in plastic containers 360 × 250 × 270 mm high. Substrate was peat moss to a depth of 100 mm set on top of aquarium gravel and fly wire, with plumbed drainage as described for the adults. Leaves provided surface level retreats and water was provided in a shallow plastic saucer 130 × 10mm. Water was replaced every two days and the substrate was flushed at the same time.

Juvenile frogs were maintained in glass aquaria 400 × 750 × 500 mm deep and furnished as described for newly metamorphosed frogs. Water was provided in a large plastic saucer 15 mm deep and 250 mm in diameter.

The lighting and temperature regime were the same as for the adults, post-July 2002.

Spawning Details

Northern clade.—Males in both northern groups called throughout the first night after arriving at the zoo. A pair in each group was in amplexus the following morning. Females spawned three times over the following seven days (13–19 February), with one female spawning twice—four days apart. Spawning subsequently occurred on 30 May 2001, and then in early September 2004 (Table 1). Spawning also occurred in 2005 and 2006, but none of those eggs were retained.

During June–July 2004, the frogs were maintained in drier conditions than previously, with flushing of the peat moss substrate reduced from every 1–2 days to approximately once or twice a week. The frogs were less active and spent most of their time buried in the peat moss, from just below the surface to 200 mm deep.

Trans-illuminating females with a small torch in early August to September 2004 suggested that they were carrying eggs. Consequently, when the next low pressure system arrived, the frogs were given a three day transition period of wetter conditions. Breeding groups received sporadic daily rain sessions consisting of 15–30 minutes, 2–3 times a day. During these sporadic rain days, plastic was used to cover 95% of the ventilation to raise the humidity within the enclosure. The humidity was increased from approximately 40% to 95%, which brought the frogs to the surface and initiated male calling. Humidity in the spawning enclosure was maintained at 100% for 24 h a day, and under these conditions the activity level of the frogs increased. Once local rain started, one adult pair was removed from the group and placed into

Table 2. Spawn date, egg, and breeding female data for southern clade *Mixophyes balbus* at Melbourne Zoo.

Spawn date	Number of eggs laid	Water temperature (°C)	Days until hatching commenced	Days until hatching finished	Percent fertile

Average	556 days	28	2.16	N = 30	

*Year following commencement of metamorphosis within the group.

Table 4. Differences recorded between northern and southern clade *Mixophyes balbus* at Melbourne Zoo.

Characteristic	Northern clade	Southern clade
Adult body length (mm)	Males: 55–57 Females: 76–77	Males: 52–57 Females: 60–62
Body length of newly-emerged metamorphs (mm)	23–32	21–23
Eggs per spawn event	120–280	260–390
Eye color	Narrow upper eye pale blue	Pale blue of upper eye less obvious. Generally darker appearance of whole eye
Banding on lower rear legs	6–7 bars and bars faint on front of legs	9–10 bars and bars more distinct
Dorsal patterning	Small number of faint darker blotches on dorsal surface	Small number of more distinct blotches, which are more consistently located along the middle of the back
Facial features	Dark patterning between eyes and nose tip less pronounced	Dark patterning between eyes and nose tip more pronounced. Nose more pointed than northern clade frogs.
Spawn site	Eggs consistently laid among gravel in riffle zone	Eggs laid in various locations, e.g. on and under rocks, among gravel, etc.

the spawning enclosure. Spawning occurred the next day and the frogs were then returned to the group enclosure. This process was repeated with two other pairs, the third pair being F1 frogs 30–34 months old (Table 1). Eggs from all three spawnings were removed and set up in aquaria as described for the tadpoles. The eggs were mixed amongst the gravel and adhered to individual rocks in small clumps of approximately 1–18 eggs.

Spawning also occurred in 2006, 2007, and 2008, but none of the eggs were retained and no data were recorded in 2007 and 2008.

Southern clade.—Frogs were observed in amplexus in mid-December 2010 and 150 eggs were laid on 23 December. The eggs hatched after 9–12 days at a water temperature of 18.7°C. The adult frogs were 5 years and 1 month old at that time. All frogs had been measured earlier in December—the three males averaged 55 mm SVL (52–57 mm) and two females averaged 61 mm SVL (60–62 mm). Nest dimensions and female weights were not recorded for the southern clade frogs. Subsequent spawning occurred in 2011and 2012, but none of those eggs were retained.

Larval Duration and Metamorphosis

Northern clade.—One group of 45 randomly selected tadpoles was taken from one spawning and tracked until each one had metamorphosed (30) or died (15). Metamorphosis took 6–30 months and occurred only between November and April in each year after metamorphosis commenced within the group (Table 2). One individual took more than five years to metamorphose (Hobbs 2014). Average water temperature during winter was 16°C (range 14–18°C) and 18°C (range 16–20°C) during summer.

Southern clade.—Seven of the 10 tadpoles received from the wild on 14 January 2005 metamorphosed from 9–20 November 2005, 300–311 days after arrival at the Zoo. Ten tadpoles from eggs laid on 23 December 2010 metamorphosed after 281–438 days. The rest of the developing tadpoles were not retained. Average weight and length of four of the frogs at metamorphosis was 1.56 g (1.25–2.01 g) and 22.46 mm SVL (21.73–23.05 mm) respectively.

PHOTO BY M. SWAN

Fig. 3. Female captive-bred northern clade *Mixophyes balbus* at Melbourne Zoo, with less distinct barring on rear legs and more obvious blue of upper eye.

Differences between Northern and Southern Clade *Mixophyes balbus*

Morphological differences were noted between the northern and southern clade *M. balbus* at the Zoo (Table 4). Southern clade frogs had darker eyes, more bands and more distinct banding on lower rear legs, more distinct and consistent dorsal markings and their noses were more pointed. Southern clade females were also smaller, laid more eggs per spawning and laid eggs in more varied locations (Figs. 2 and 3).

Discussion

Northern clade.—The founding individuals were collected in February 2001 towards the end of the breeding season. Males were calling at the time and presumably the females had come down to the stream to breed. Consequently, it was no surprise that spawning occurred shortly after the individuals were placed together following their arrival at the Zoo. Spawning by wild females has been recorded in February (Lewis 2000).

Over the frogs' first winter in Melbourne, it became evident that the frogs at the Zoo were experiencing higher temperatures than would be the case in the wild at that time of year, ie. 18–23°C at the Zoo vs. 7–15°C on the Timbarra Plateau. This probably explains the spawning which occurred in May 2001 during winter, a time that the species is not thought to breed in the wild. It could be construed that the frogs were experiencing an "extended" summer and it was feared that by not experiencing normal winter temperatures, the extrinsically influenced spermatogenetic and ovarian cycles might be negatively affected and detrimental to subsequent breeding seasons (see Duellman and Trueb 1994). Moving the frogs to a room with the required temperature regimes in July 2002 allowed them to experience natural annual temperature cycles from that time.

The frogs received sporadic rain events throughout the 2003/2004 breeding season and although they were observed in amplexus on many occasions, the females failed to spawn. Spawning in the wild follows heavy rains, when the water level of the stream is receding (Knowles et al. 1998; Lewis 2000; B. Lewis, pers. comm.). It was clear that the captive rain conditions did not provide the trigger to instigate spawning and it may be that the captive rain and humidity conditions were not well defined or distinct enough from the non-breeding conditions. Subjecting the frogs to more distinct seasonal conditions, commencing with a dry period in the 2004 winter over the non-breeding season, followed by a "distinct wet season," was successful as three spawnings occurred in late 2004. Similar behavior has

been recorded in leptodactylid frogs in the genus *Ceratophrys* in South America that occur in similar heathland habitat subject to distinct wet and dry seasons (Duellman and Lizana 1994; Ortiz et al., *in press*).

Egg numbers per spawn event increased with increasing female age in northern clade frogs. In most amphibians, egg numbers increase with female weight, which is often correlated with age (Whitaker 2001). This is most likely to have been the case with the *M. balbus* at Melbourne Zoo.

The first northern *M. balbus* tadpoles to metamorphose were smaller and weighed less than their siblings which metamorphosed later. A similar result has been found in Southern Corroboree Frogs (*Pseudophryne corroboree*) bred at Melbourne Zoo and it is suggested that the longer larval period in this species allows for more robust metamorphs, which is beneficial to the later development of those individuals (McFadden et al. 2013). In general, longer tadpole life leads to larger metamorphs and juvenile frogs, although the studies that have experimentally tested this phenotypic plasticity in frogs have done so by investigating the impacts of other factors, such as presence of a predator and food availability, rather than the relationship between length of larval duration and metamorph size in itself (Nicieza 2000; M. Mahony, pers. comm.).

The single northern *M. balbus* tadpole that took more than five years to metamorphose was maintained under the same conditions as its siblings, apart from individual housing after all other siblings had metamorphosed. Environmental factors that can effect larval duration between groups of larvae, such as temperature and conspecific density (Loman 2004), do not explain why this individual did not metamorphose over the same period as its siblings (Hobbs 2014).

Southern clade.—The numbers of eggs laid in each spawning by the females at the zoo were within the range recorded for *M. balbus* in the wild by Anstis (2002). The number of eggs per spawning was higher in the southern clade frogs than the northern clade frogs.

Northern and southern clade frogs both exhibited what appeared to be distinct, but similar, spawning periods, e.g., February, April–May and August–September for the northern frogs; and December–February and August–September for the southern frogs, although the April–May spawning by the northern clade frogs may have been an artifact of captivity, as previously noted. Allowing for the small sample size, this suggests minimal differences in the seasonal pattern of reproduction between the two clades, under the same captive conditions. There are very few published accounts of spawning in the wild in this species (NPWS 1998), so it is not possible to say whether the spawning periods recorded at Melbourne Zoo reflect wild behavior or are an artifact of captivity. Many anuran species have extended 'breeding seasons' over many months, within which individual females may spawn on more than one occasion (see Duellman and Trueb 1994). Multiple spawning in a single season has been recorded in a range of other anurans, including *Chiromantis xerampelina* (Jennions et al. 1992), *Hyla cinerea* (Gunzberger 2005), and *Litoria infrafrenata* (Banks and Leyden 1990). Recognizing how little is known of the annual reproductive cycles of wild *M. balbus*, it may be that this species is capable of breeding from August to February if conditions are suitable. Further field work with this species would help to clarify if the findings reported here are artifacts of captivity, or reflect wild behavior.

Although based on small numbers of frogs collected at single sites, and hence with a high likelihood of being related, differences were observed between the northern and southern clade *M. balbus*. It is not possible to say to what degree these differences reflect consistent differences between frogs in the wild, as wild southern clade *M. balbus* have received very little attention. However, differences in the thickness and number of bands on the legs of wild frogs from the two clades have been observed (M. Mahony, pers. comm.).

Breeding of *M. balbus* at Melbourne Zoo proved to be straightforward, providing the basis to address one of the key actions in the National Recovery Plan for the species should it be needed, ie. "Establish a captive breeding program capable of augmenting reintroductions of Stuttering Frogs at selected extinction sites or for enhancement of extant populations" (Hunter and Gillespie 2011).

Acknowledgments.—We thank A. Martin and M. Mahony for comments on the early drafts of the manuscript. Keepers in the Herpetofauna Department at Melbourne Zoo maintained the frogs, eggs and tadpoles throughout this program at the Zoo. The northern clade frogs and tadpoles were collected and held under New South Wales (NSW) National Parks & Wildlife Service Scientific Licence No. S10020, NSW Agriculture & Statistical Reference No. 2365, NSW State Forests Special Purposes Research Permit No. 05558, and Zoos Victoria Animal Experimentation Ethics Committee Project No. ZPGB 00002R. The southern clade tadpoles were collected under NSW National Parks and Wildlife Service licence No. S11495, and NSW Department of Conservation Animal Ethics Committee No. 041025/02.

Observations on the Captive Maintenance and Reproduction of the Balcones Barking Frog, *Craugastor augusti latrans*

Craugastor augusti (Anura: Craugastoridae), the Barking Frog, is a direct-developing species ranging from parts of the southwestern United States southward into Mexico. In the northern parts of the range, Barking Frogs are rarely encountered as they are only surface active for a few weeks following the onset of heavy spring and summer rains (Stebbins 2003; Tipton et al. 2012). Because of their secretive nature, Barking Frogs are notoriously difficult to study (Goldberg and Schwalbe 2004a). In the Edwards Plateau region of central Texas, the Balcones Barking Frog (subspecies *C. augusti latrans*; see Zweifel 1956) is active from late February to early April (Conant and Collins 1998). An early and often cited observation is that this subspecies has the behavior wherein males attend the eggs (Jameson 1950). This report contrasts with radio-telemetry data that suggests another subspecies in Arizona (*C. a. cactorum*) has the female as the attending parent (Goldberg and Schwalbe 2004b).

Herein we describe the maintenance of a small colony of Barking Frogs, report an instance of captive reproduction, and describe observations of female parental care in *C. a. latrans* that were collected in early 2013. To the best of our knowledge, this is the first documented captive hatching of *C. augusti*. Given previous reports of male parental care in *C. augusti latrans* (Jameson 1950), our observation of female nest attendance adds a new element to the discussion of parental care mode in this enigmatic frog.

Specimen acquisition and husbandry methods.—During the early spring of 2013 (March–April) we collected 18 adult Barking

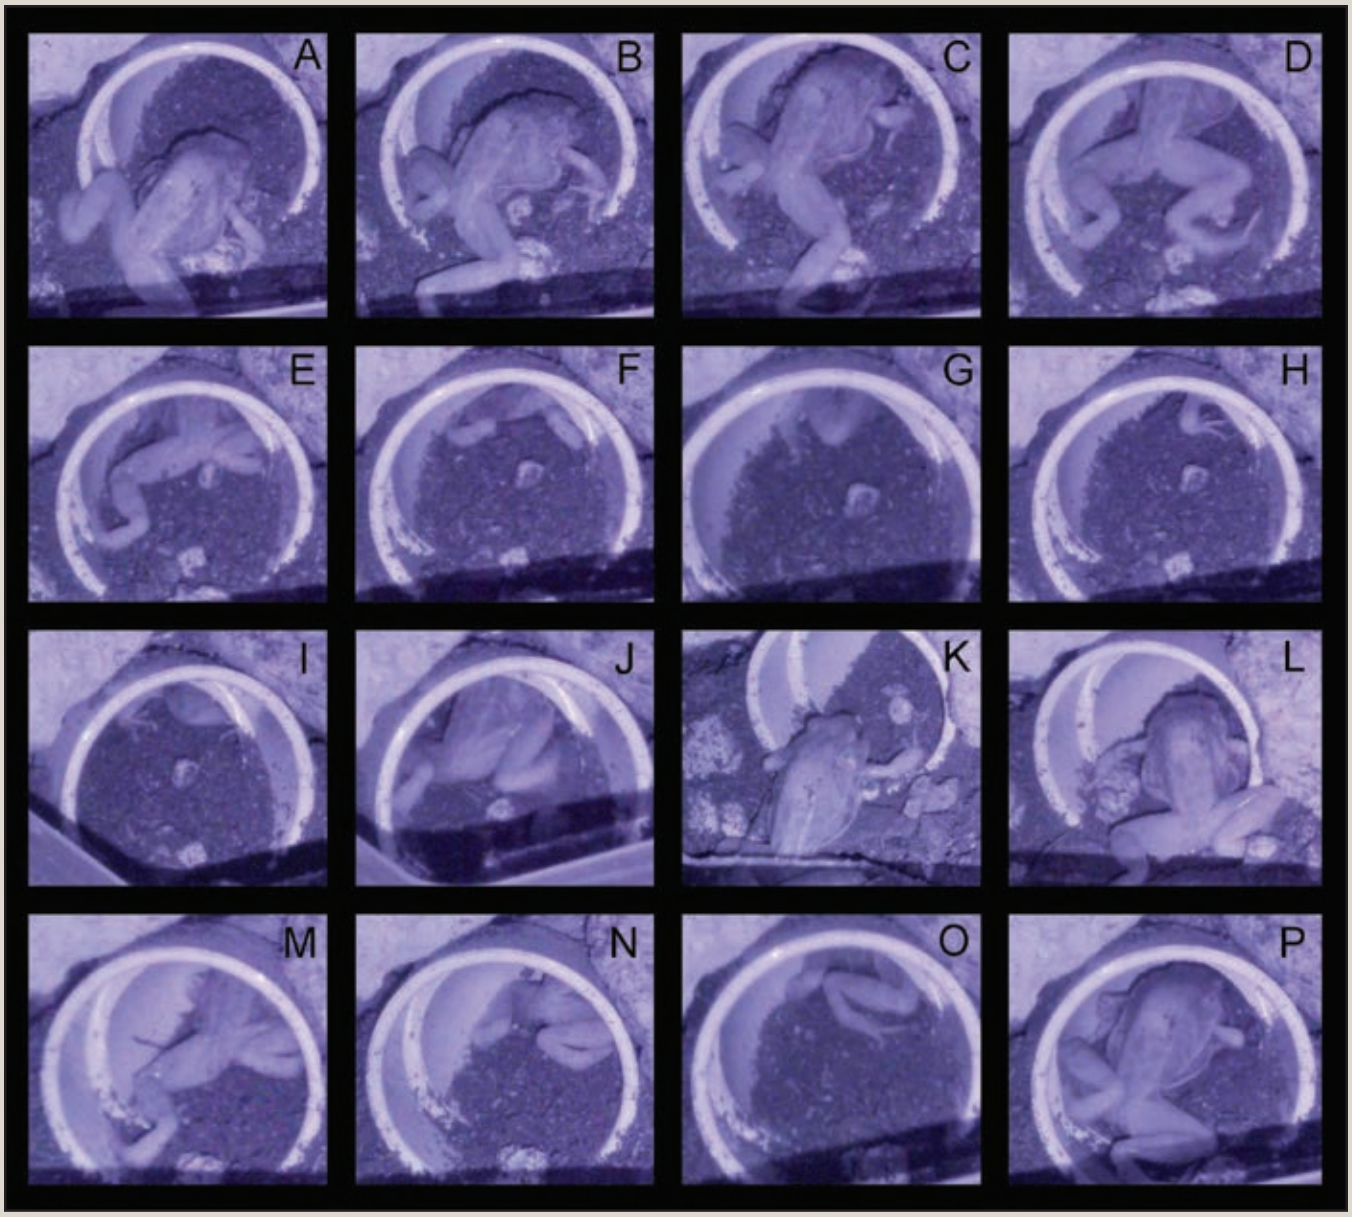

FIG. 1. Images from a video taken of a female *Craugastor augusti latrans* constructing a nest on 24 April 2013 at 2300 h.

Frogs from central Texas. All specimens were collected in Bandera, Edwards, and Real counties. We acquired these individuals by road cruising immediately following heavy spring rains, which often featured substantial hail. Frogs were subsequently maintained at the University of Texas at Arlington (UTA). All frogs were maintained in a large walk-in environmental chamber (Environmental Growth Chambers, Chagrin Falls, Ohio, USA) kept at a constant 22°C with a 12:12 h light/dark cycle. Individual frogs were maintained in plastic shoeboxes (33 cm × 19 cm × 10 cm or 38 cm × 26 cm × 14 cm) with holes drilled to allow ventilation. The typical enclosure contained a hiding area (either a rain gutter pipe or a PVC sewage pipe) and substrate consisting of a mixture of sphagnum moss and soil from central Texas. We kept the room humidity at 40%; humidity levels within individual enclosures were ca. 70%. All enclosures contained a plastic water dish (12 cm × 8 cm × 2 cm) that was changed one to three times a week. We lightly misted enclosures following each water change. All frogs were offered 2–3 adult crickets once weekly. We diagnosed sex based on vocalization (males) and visualizing eggs through the ventral surface (females).

Breeding and nest construction.—Shortly after field collection, captive males were frequently heard calling and most captive females had eggs visible through the ventral surface. Thus, we attempted to observe breeding interactions in captivity. On 4 April 2013, we placed a male (field number: JWS 692) and a female (field number: JWS 688) from Real County together in a large plastic enclosure (38 cm × 33 cm × 33 cm). Based on Jameson's (1950) description of oviposition site, we acquired substrate (soil and rocks) from near the collection locality in central Texas. On 21 April 2013 at ca. 2000 h, we noted the female moving dirt into the PVC pipe. We recorded a portion of the nest construction using an infrared "night-vision" digital video camera (Bell-Howell, DNV16HDZ). Over the course of the evening the female kicked soil into the pipe (Fig. 1; A–E, K–N) and then compressed it using her body and limbs (Fig. 1; F–I, O–P). Unfortunately, we did not directly observe oviposition,

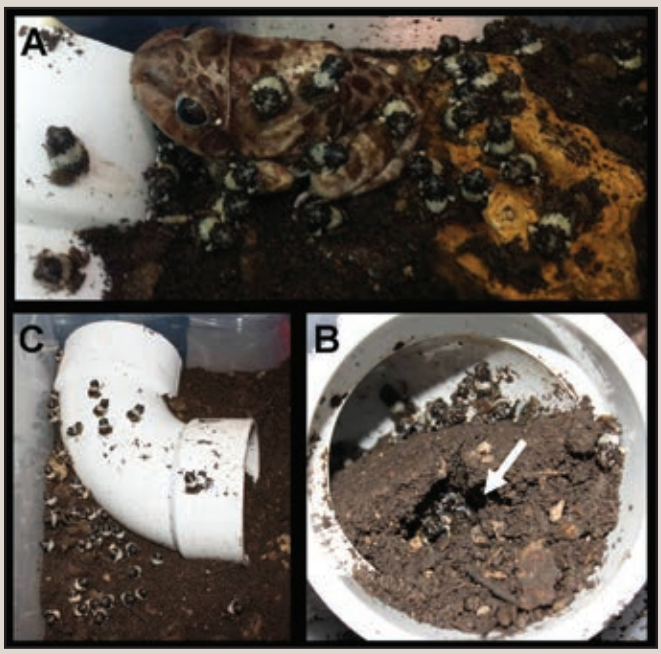

Fig. 2. (Clockwise from top): A) *Craugastor augusti latrans* froglets with female parent shortly after hatching; B) end of PVC pipe where nest cavity (indicated by a white arrow) was exposed; and C) hatchlings moving around the enclosure.

amplexus, or any other reproductive interactions prior to the nest construction.

During the construction of the nest the male remained hidden under a rock in the enclosure. The female sat continuously inside the PVC pipe on top of the nest from 21 April to 04 June (her position was checked several times a day). From 21 April to 05 May 2013, the male remained outside of the PVC pipe and we only observed him entering the pipe when in pursuit of food items. On 06 May 2013 the male was removed to ensure that he would not consume any of the offspring once they hatched, and we removed the water dish to ensure no hatchlings would drown.

Froglet emergence and maintenance.—On 04 June 2013 we discovered 119 froglets in the enclosure with the female. Careful excavation revealed a nest cavity in the back of the PVC pipe (Fig. 2B). In the cavity we found three undeveloped eggs which made the total clutch size 122. We maintained the froglets in groups of ten in large circular deli containers (ca. 20 cm × 10 cm). The deli containers contained sphagnum moss (Besgrow Sphagmoss, Christchurch, New Zealand), soil from central Texas, and an inverted plastic weigh tray as a refugium. Immediately after hatching we offered the froglets wingless fruit flies (*Drosophila melanogaster*) and pinhead crickets (*Acheta domestica*). We also periodically offered a larger flightless fruit fly species (*D. hydei*). Although hatching success was high, froglet mortality was also high and by 10 August 2013, 75% of the brood had expired. As of 15 October 2013, the remaining 30 individuals were growing rapidly and thriving. Discerning whether the high mortality rate was related to issues of husbandry or natural history will require additional trials.

Conclusions.—The large clutch size we report for *C. augusti* (N = 122) is not unexpected given the relationship between body size and clutch size that has been documented across terraranan species (Wake 1978). All hatchlings possessed a striking white dorsal band that is not observed in adults. This trait has been previously described (Stebbins 2003) and is of note because few frog species exhibit distinctive ontogenetic color pattern shifts (Kraus and Allison 2009). Although our observations of captive reproduction in *C. augusti* shed light on some issues such as parental attendance and clutch size, many questions remain including those related to the modality of parental nest attendance and the occurrence of amplectant behavior. Furthermore, *C. a. latrans* occupies some of the most extreme habitat (in terms of aridity and seasonality) experienced by *C. augusti*, so aspects of its natural history and reproduction may be outliers compared to other barking frog subspecies. Thus, future examinations of populations from across the species' range in Mexico and elsewhere in the U.S. will be necessary to elucidate whether the patterns we observed in *C. a. latrans* are broadly applicable to other barking frog lineages.

Acknowledgments.—We thank Branden Williams, Alphas Wicker, and the UTA IACUC committee for their assistance with establishing the barking frog colony at UTA (IACUC protocol A.13.011 to M. K. Fujita). Carl Franklin kindly assisted with acquiring scientific collecting permits from the Texas Parks and Wildlife Department (permit SPR-0707-1387). We thank Corey Roelke, Elijah Wostl, and Jessica Maxcy for assistance with field work. We thank John Malone and Caren Goldberg for discussions on barking frog natural history and captive maintenance. Funding for maintaining the barking frogs used in this study was supplied by start-up funds to MKF from UTA.

Preliminary Experiences with the Husbandry, Captive Breeding, and Development of the Hispaniolan Yellow Tree Frog, *Osteopilus pulchrilineatus* (Amphibia: Anura: Hylidae), with Ecological and Ethological Notes from the Wild

Osteopilus pulchrilineatus (Cope 1839) is the smallest of the four species of hylid frogs in Hispaniola. Females reach 43 mm SVL with males being smaller, at 39.5 mm (Henderson and Powell 2009). This frog is easily distinguished by having a dorsal pattern consisting of three conspicuous yellow lines on different tones and shades of yellow, tan, green or chocolate-brown (Fig. 1). Lower flanks are yellow. Dorsal lines are more or less evident depending on color phase. This species has a scattered distribution throughout the island, from sea level to moderate altitude, and seems to be locally abundant. This frog was considered Endangered (EN) by the IUCN Red List, due to the increasing loss and fragmentation of habitats (IUCN 2013; Stuart et al. 2008). The species was assessed as requiring additional *in situ* conservation action during the Caribbean Amphibian Ark Conservation Needs Assessment of 2011. More recently, *O. pulchrilineatus* has been considered highly vulnerable to climate change by Foden et al. (2013). Eggs and tadpoles of *O. pulchrilineatus* remain undescribed (Henderson and Powell 2009), although it was assumed that early development occurs in still water (IUCN 2013). Vocalizations have been reported (Schwartz and Henderson 1991), but no data on temporal and spectral acoustic parameters exist.

The importance of developing husbandry protocols and captive breeding programs for endangered species of amphibians have been discussed (Gascon et al. 2007; Reid and Zippel 2008; Zippel and Mendelson 2008; Zippel et al. 2011). Captive maintenance and breeding has the dual function of providing basic information on species biology (often absent or hard to obtain in the wild) and, most importantly, to favor conservation by combining complementary *ex situ* and *in situ* actions. This is crucial for amphibians in which populations are fast declining due to loss of suitable habitats, emerging infectious diseases, the impact of introduced species, over-collection, and other threats. It is also a preventive strategy for populations that might continue to decline in the near future due to these and other causes.

Herein, we discuss the first successful experiences with husbandry and breeding of *Osteopilus pulchrilineatus* in captivity, together with some ecological and ethological information obtained from the field. The limited observations and short term of this study determine its preliminary character. However, since this species is endangered and little is known about its biology, the information provided would be useful as a baseline to encourage future efforts to establish a standard protocol for long-term *ex situ* conservation programs.

Terms and measurements.—Terminology related to eggs and clutch structure follow Altig and McDiarmid (2007). The Gosner (1960) system was used for larval staging. Measurements were taken with a caliper (0.5 mm accuracy) under a dissecting microscope (Swift M27LED). Frogs were weighed with an AWS® AC-100 Digital Scale (100 × 0.01g). Calls were recorded with a Marantz Professional PMD 661 digital recorder and a Sennheiser ME 66 microphone. Acoustic signals were digitized at 48 kHz and a sample size of 32 bits. Acoustic analysis was performed with the software BatSound 2.1 (Pettersson Elektronic AB © 1996–1999). Sonogram was generated with a FFT (Fast Fourier Transform) of 512 points, using Hanning windows. Temporal variables were all measured on an oscillogram, and the dominant frequency was taken as the highest peak of energy in the power spectrum.

Observations in the wild.—This section has information obtained during fieldwork in the summers of 2011 and 2012. *Osteopilus pulchrilineatus* was observed in a wide range of ecological situations. Frogs were active at night at temperatures of 24–27°C and relative humidity of 82–90%. The species was associated with six types of breeding habitats (Fig. 2): 1) permanent ponds with grassy vegetation and ferns in open grassland; 2) small ponds in forested mountain areas; 3) pools along intermittent streams in

PHOTOS BY NILS NAVARRO (A) AND LUIS M. DÍAZ (B–C)

FIG. 2. Some breeding habitats of *Osteopilus pulchrilineatus*. A) Pond about 100 m long in open grassland at the surroundings of Juana Vicenta, Samaná Province, where species is sympatric with *Osteopilus dominicensis*; B) puddle in grasslands that are often used for rice fields in Río Limpio, Reserva Natural Nalga de Maco, Elias Piña; C) forested edges of Cañada de Quilino, Reserva Natural Nalga de Maco, Elias Piña, breeding place of the four hylid frogs of Hispaniola: *Hypsiboas heilprini, Osteopilus dominicensis, O. pulchrilineatus* and *O. vastus*.

mountain forests; 4) small ephemeral pools along trails in forested areas; 5) pools and puddles in rice fields; and 6) margins of rivers and streams with gallery forests. Breeding sites were always lentic habitats of standing or slow-moving water. In some localities, the species was associated with other hylid frogs like *Osteopilus dominicensis* (lowland and highland habitats), *Hypsiboas heilprini*, and *O. vastus* (highlands). Tadpoles were found sympatrically with those of the other Hispaniolan hylid frogs at Río Limpio, Nalga de Maco Natural Preserve (Elias Piña Province).

Males generally called from small shrubs and grasses, usually less than 1.5 m high, rarely up to 3 m. Advertisement calls of ten males recorded in Loma La Canela, Cordillera Central (100 calls in total) were pulsatile in structure, having 11–19 pulses (Fig. 3) with pulse duration of 3–5 milliseconds. Pulses were narrowly spaced at the beginning of each call (8–9 milliseconds), becoming more spaced in the middle (24–62 milliseconds), and very narrowly spaced in the last 3–5 pulses (4–6 milliseconds). Call duration was 0.3–0.4 seconds. Call intervals were 0.8–1.5 seconds with a repetition rate of 47–64 calls per minute. The dominant frequency was 1.8–3.2 kHz.

Three egg clutches were observed in shallow water (Fig. 4), hidden among grasses at the edge of a forest pond, or fully exposed over beds of algae in pools along intermittent streams. Each clutch was a floating film of eggs. Clutch jelly matrix was somewhat thicker than those observed for *Osteopilus dominicensis* (pers. obs.). Tadpoles were seen swimming in all habitats, in depths that ranged from 2–60 cm. Larvae were exposed on the bottom, or hidden among grasses and algae.

Acquisition of adults and husbandry.— We began with four individuals: one male and a female were collected in the surroundings of Juana Vicenta, Samaná Province on 20 August 2011; one male was collected on 16 September 2011, at Río La Travesía, Loma La Canela, Ébano Verde Natural Preserve (Duarte Province), and an additional female was collected 9 July 2012 from Río Limpio, Nalga de Maco Natural Preserve (Elias Piña Province). After a quarantine period of two months, following general guidelines (Browne et al. 2007; Lynch 2001; Wright and Whitaker 2001), the frogs were accommodated in an all-glass silicone-glued aquarium (75 × 40 × 50 cm) that was modified as an indoor terrarium (Fig. 5). The bottom was drilled out, a bulkhead was installed, and a 19-mm-diameter plumbing system allowed for controlled drainage of the terrarium and the continuous discarding of overflowing water. A false bottom was made from a plastic light diffuser and plastic screening. It raised a basal layer of gravel (diameter ~4–5 mm) about 3 cm from the bottom glass. Half of the terrarium was a 7-cm-depth aquatic section ~17 liters in capacity, delimited from the land section by flat rocks. Water was filtered through the terrarium gravel by using a submerged water-pump (Exoterra©; model PT 2095) with a small waterfall output. The pump was placed inside a plastic chamber for easy access, and two cartridges for chemical filtration (activated carbon and zeolite) were situated in the pump inlet. The pump chamber was made from plastic mesh to allow water flow.

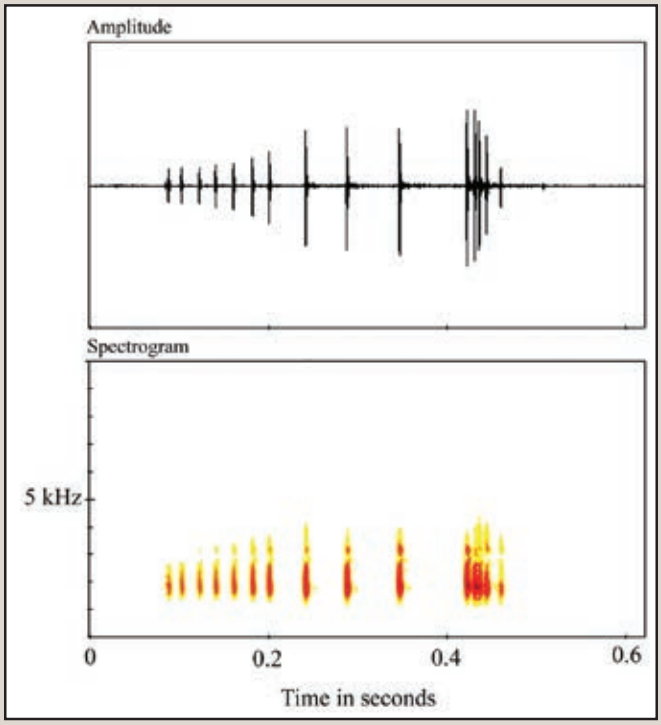

FIG. 3. Waveform and spectrogram of an advertisement call of *Osteopilus pulchrilineatus* from Loma La Canela, Cordillera Central, Duarte Province; 20 h; 15 September 2011; temperature: 25°C.

PHOTOS BY LUIS M. DÍAZ

FIG. 4. Two egg groups of *Osteopilus pulchrilineatus* photographed in the wild at two localities in the Dominican Republic. A) Embryos around Gosner Stage 16 in a water film over dead leaves in a temporary puddle in an intermittent adventitious slow stream aside Río La Travesía, Loma La Canela, Cordillera Central, Duarte Province. B) Embryos close to hatching, floating over a compact mass of algae in the slow-flowing water of a pool fed by an intermittent stream in the surroundings of Río Limpio, Reserva Natural Nalga de Maco, Elías Piña.

The water had a pH of 7.6, and 660 µS of conductivity. In the land section, the underlying gravel was thicker, covered with tree-fern fiber substrate, and planted with *Scindapsus* sp. and *Calathea* sp. The first plant species became the dominant vegetation. Ammonium, phosphates, nitrites, and nitrates were regularly monitored and kept within safe ranges (Wright and Whitaker 2001). The terrarium cover had an access window and was built from a plastic light diffuser, PVC sheets, and a plastic mesh (3.5 mm). The mesh comprised 50% of the cover, to allow the placement of lights and ventilation. Cooling fans were installed on the terrarium cover to force ventilation, and to avoid over-heating and water condensation on the glass. An artificial rain system (made from a high pressure pump: Lucky Reptile© SR-1, and two nozzles near each end of the terrarium) was activated for one minute twice each day and controlled by a digital timer (Woods© model 59377). Two lamps were used: a Nisso© plant growing fluorescent tube and an Exoterra Repti Glo© 5.0 (15 W). Both fluorescent lamps promoted healthy plant growth; however, Lindgren et al. (2005) documented the low effectiveness of the UVB emission by Exoterra Repti Glo© 5.0 tubes compared with other lamps available for herpetoculture. In March 2012 two Eiko© Halogen lamps were installed over the terrarium cover, and were switched on for two hours at 0900 h and at 1600 h. We have no information on the UVB needs of this species, but for other hylid frogs this factor was demonstrated to be important for normal growth and health (Verschooren et al. 2011). The frog room was kept at ambient temperature and humidity fluctuations. The terrarium was placed in a naturally illuminated room, and lamps were programmed by a digital timer to duplicate a natural photoperiod. A data logger (HOBO© Pro V2 Onset) was installed and programmed to gather data of relative humidity (RH) and temperature every 30 minutes for 1.2 years (Fig. 6).

Terrarium maintenance.—The water was changed twice weekly by partial to full draining of the aquatic section. Fluorescent lamps were replaced after one year. The water-pump filtering sponge was cleaned once weekly. Cartridges for chemical filtration were changed once a month. Dried plant leaves were removed and plants pruned as needed. Frog feces were regularly removed from the surface of leaves, rocks and glass, washing them with manual high-pressure water spraying. Water quality was monitored at least once weekly.

Feeding.—Basic food consisted of captive raised tropical house crickets (*Gryllodes sigillatus*) and cockroach nymphs (*Blatta orientalis*). Adult frogs were fed crickets three times a week and cockroaches only once per week. Prey insects did not exceed 1 cm in total length. Each frog ate 1–5 prey items at each feeding. Females often ate more than males. Insects were gut-loaded with a high protein and calcium food 48 h before being offered to the frogs. Prey items were dusted with Repashy Super Foods© Calcium plus ICB (Repashy Ventures, Inc.). Froglets were fed daily with pin-head crickets and once a week with tiny cockroach nymphs, all dusted with the same supplementation as the adults. Prey size and number was gradually adjusted as they grew.

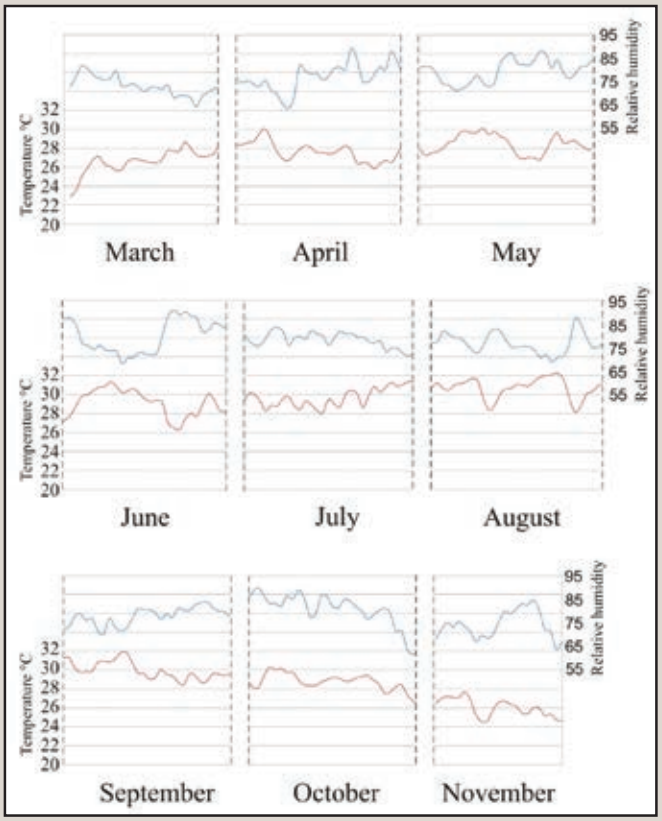

FIG. 6. Variation in temperature and relative humidity from March to November 2012.

PHOTOS BY LUIS M. DÍAZ

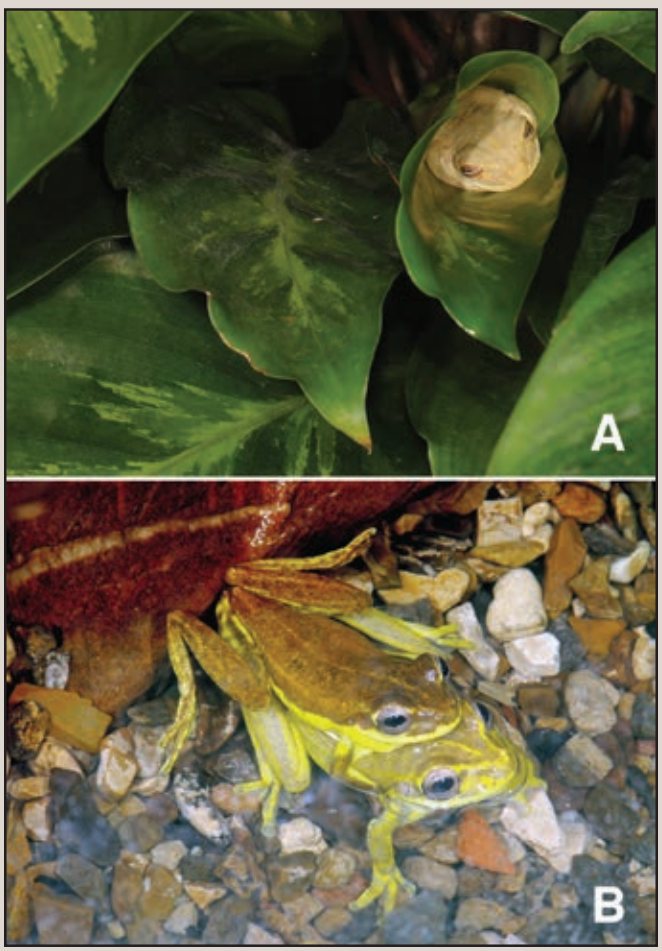

FIG. 7. Female *Osteopilus pulchrilineatus* sleeping in a rolled leaf of *Calathea* sp. (top). Amplecting pair in the water section of the terrarium (bottom).

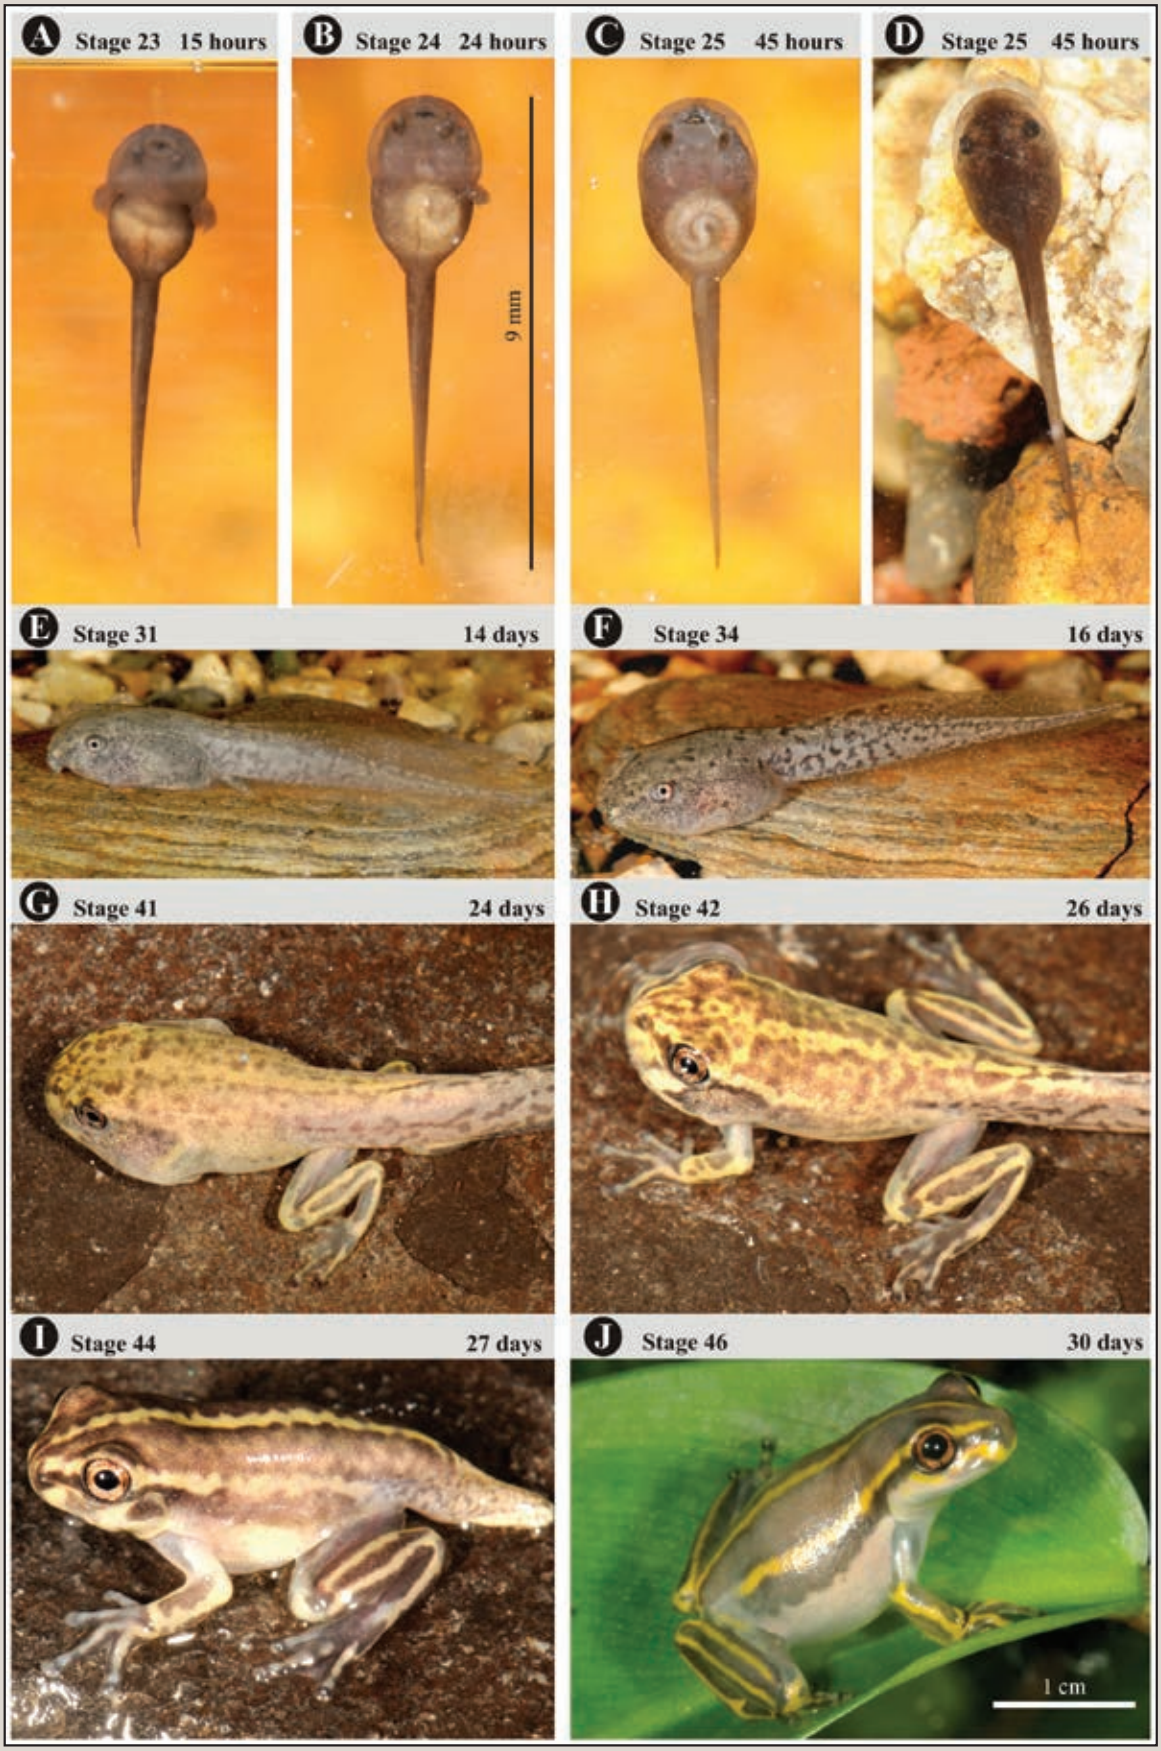

Captive behavior.—Captive specimens were nocturnal. Soon after frogs began waking up they shed and ate the outer layer of skin, moving their legs and opening their mouths to swallow the tissue. During the day, frogs rested on leaves or inside rolled leaves (Fig. 7). Very often frogs were observed sleeping during the day on the concealed side of the leaves away from direct light. Other refuges were among rocks or in pockets at the base of plants. Males called from plant leaves, rocks, or the terrarium glass, distending a single, somewhat laterally lobed, yellow vocal sac (Fig. 1). Calling males sometimes interacted by jumping toward one another, displacing each other from perches, while producing clicking calls. Amplexus occurred at night (Fig. 7). On a few occasions, amplectant pairs were observed resting during the day. Like other hylid frogs, this species was observed catching prey by jumping on them from some distance.

Captive breeding and early development.—In our experience, *Osteopilus pulchrilineatus* was an opportunistic breeder, avoiding reproduction at temperatures that were below 24°C for an extended period and the driest periods. Frogs tended to be lethargic at temperatures that were near 32°C for a long time. Females produced oocytes throughout the year. Frogs were particularly active on warm, cloudy, or rainy days, but reproduction was observed under very dissimilar conditions. They usually bred at temperatures between 25–29°C, and a relative humidity over 75–80%. A decrease in atmospheric pressure seemed to be another stimulus for this species. Oviposition was always preceded by intense vocal activity, with adult males usually changing to a vivid yellow coloration. Amplexus was axillary (Fig. 7). The first egg clutch was found on 2 May 2012, after heavy outdoor rain. Seven egg clutches were obtained from 2 May 2012 to 18 May 2013. The egg clutch laid on 2 May 2012 had 327 eggs and one obtained on 11 February 2013 had 463 eggs. The exact number of eggs from the other clutches was undetermined. Clutches usually consisted of two or three groups of eggs that were apart from each other. Each group often had approximately 100–200 eggs, or less frequently as low as 50 eggs.

PHOTO BY LUIS M. DIAZ

FIG. 10. Tadpole in Gosner Stage 31 with scoliosis.

At least three of the six observed clutches were laid around sunrise.

Clutches were laid on the surface of the water. At the beginning, the egg masses were somewhat compact but soon thereafter expanded as a one-egg-thick layer. Eggs were black (animal pole) and white (vegetal pole) as in other hylid frogs, and measured 1.4–1.6 mm in diameter. The eggs hatched after 25–30 h at 28–30°C. Embryonic development occurred very quickly at these temperatures but might be longer at lower temperatures. Representative embryonic stages in a chronological order are shown in Fig. 8. Hatchlings remained fixed to the vivarium glass, different objects, or even other eggs by means of a mucous secretion from the adhesive glands (Fig 8). After 15–16 h the larvae still had external gills, but 24 h later only one remained (Fig. 9A-B). After 40–48 h from hatching, larvae started swimming and searching for food (Fig. 9C–D).

Tadpoles metamorphosed in 26–40 days at 28–32°C. After 14 days from hatching, tadpoles were usually at Gosner Stages 30–31 and measured 29.3–33.6 mm (mean = 31.4 mm) in total length (Fig. 9E). After 16 days (Fig. 9F) they reached stages 33–35, measuring 33.7–38.4 mm (mean = 35.6 mm). Stages 36–37 were reached in 18 days, and the tadpoles were 36.1–40.8 mm (mean = 38.4 mm) in length. After 24 days (Fig. 9G) most tadpoles were in stages 40–41, and reached 40.0–48.4 mm (mean = 44.2 mm). The first individuals in stage 42 were usually found after 26 days. A tadpole in stage 44 is illustrated in Fig. 9H, and another in stage 45 in Fig. 9I. Two days later, recently metamorphosed frogs measured 13.6–15.1 mm (mean = 14.4 mm) snout–vent length (Fig. 9J). Tadpoles from different clutches, and even from different females, grew at a similar rate and in a quite synchronous way, but a few showed delayed metamorphosis. We estimated a tadpole survival rate of 90–95%, excepting those from the first clutch that developed scoliosis (see tadpole diseases below).

Tadpoles were reddish brown or grayish brown, with a profusion of iridocytes. The caudal muscle was somewhat lighter than the body and speckled or with a vermiculated pattern. Caudal fins had the same pattern as the caudal muscle or were immaculate. The eyes were dark brown from above; golden colored in the lateral view; the pupil was bordered by a yellow ring. Ventral coloration did not differ substantially from dorsal coloration, and was somewhat translucent or had scattered iridocites. The tadpoles raised in spartan tanks were grayish colored and exhibited more conspicuously vermiculated tails than those raised in tanks with gravel on the bottom, which were more reddish-brown in color with more speckled tails. The second condition is almost identical to that of tadpoles found in the wild. Tadpoles after Gosner Stage 36 gradually showed the yellow striping on the dorsum and hind limbs typical of the species (Fig. 9).

Tadpole husbandry, feeding and diseases.—Hatchlings were left in the aquatic section until they started swimming actively for food. At that time they were carefully siphoned and removed to separate tanks. If tadpoles were left in the aquatic section of the terrarium they ate eggs and hatchlings of new clutches. Tadpole rearing tanks were 55-liter Sterilite© plastic boxes (58.7 × 42.9 × 31.8 cm) filled with 30 L of water. Artificial lighting (programmed for 8 hours) was provided by means of Eiko® Supreme halogen lamps hung 55 cm above the water. Tanks were placed near a glass window through which they received diffuse natural light and a natural photoperiod. We kept medium densities (sensu Browne and Zippel 2007) of 5–8 tadpoles per liter. Two husbandry methods were used:

Method 1.—In the first attempt (May 2012), flat rocks were dispersed on each tank bottom to provide a natural substrate, but the tank was essentially spartan for ease of cleaning. Water was filtered by using a synthetic sponge and active carbon. Water quality was monitored every day for nitrites, nitrates, and phosphates. Water temperature ranged from 28–29°C, and pH was 7.8. Partial water changes (50%) were made twice daily, always removing debris from the tank bottom. Tadpoles were fed 3–4 times per day, with a combination of tropical marine fish flake food (Nutrafin® Max) and calcium (~1%, Tetra® Rep Cal). Artificially raised brown algae were also added. Algae remained for a longer time in the tank to allow grazing. After 12 days about 75% of surviving larvae in Gosner Stages 30–31 developed scoliosis (Fig. 9). Immediately, extra supplementation was provided (Repashy Superfoods® Calcium plus ICB). Tadpoles that started with problems became worse and were sacrificed. The remaining tadpoles metamorphosed normally after 30–40 days. A sample of 30 apparently healthy frogs was reared until they reached adult condition.

Method 2.—For all the other experiences, a gravel biological filter was installed on the bottom of tanks. Flat rocks were also added. Partial (50%) water changes were made daily. Active carbon was not used. Food was changed to a formula based on 50% Nutrafin® Basix + New Life Spectrum® color enhancing marine pellets, and 50% Spirulina powder. A homogeneous and compact mass of food was prepared, and small pieces were dispersed in the tank. Repashy Superfoods® Calcium plus ICB was added to the formula. Tadpoles were fed 3 times daily. Nitrite levels were very low, but nitrates increased after 48 h. Under these rearing conditions we do not recommend partial water changes more than two days apart. This husbandry method proved to be excellent for tadpoles; they showed a natural coloration and behavior and metamorphosed within the range of 26–40 days. No sign of scoliosis was observed.

Food consumption increased with larval growth. The turgid shape of tadpoles and activity patterns were used as indicators that they were eating enough. Tadpoles showed cannibalism on growth-retarded individuals. This behavior was observed until the second week after hatching, but greatly diminished later, when differences in size between larvae were smaller. Cannibalism has been observed to be common in tadpoles of the Cuban Tree Frog, *Osteopilus septentrionalis* (Crump 1986).

Development and sexual maturity.—The 30 metamorphosed frogs obtained from the first clutch were split into three groups of 10 frogs each in small (40 × 32.5 × 31 cm) plastic vivaria (Exoterra® Faunarium). The only furnishing was a potted *Scindapsus aureum* that served as refuge and provided perching surfaces. One corner of each terrarium was drilled to provide drainage. The vivaria were inclined to form a small aquatic section on one side. Containers received the same lighting as the adult enclosures and were cleaned three times weekly. In two months, frogs reached 22.2–30.1 mm (mean = 26.7 mm) and weighed 0.6–1.5 g. The first calling males with nuptial excrescences were observed two months post-metamorphosis, and females with evident black oocytes through the groin skin were observed after three months. This suggested reproductive maturity was reached quickly at the temperatures provided. At six months, females measured 32.7–36.2 mm (mean = 34.5 mm) snout–vent length and weighed 2.5–3.8 g (mean = 3.2 g); males 28.4– 31.0 mm (mean = 29.3 mm), and weighed 1.3–1.9 g (mean = 1.7 g). In this sample, sexual proportion was 47% females and 53% males.

Acknowledgments.—This paper is an outcome of the project entitled "Anfibios Amenazados y Cambio Climático en República Dominicana" (Endangered Amphibians and Climatic Changes in Dominican Republic), financed by Ministerio de Educación Superior, Ciencia y Tecnología, FONDOCYT 2008-1-A-102, of Dominican Republic. Many thanks to Grupo Jaragua (Santo Domingo) for administrative and logistic support, and the Museo Nacional de Historia Nacional de República Dominicana, with especial gratitude to Y. Arias, C. Mir, C. Suriel, M. Abreu, and C. Nivar. We also thank the authorities of Museo Nacional de Historia Natural de Cuba, Agencia de Medio Ambiente (CITMA, Cuba), and Sociedad Cubana de Zoología for supporting the Cuban participants of the Project. We thank P. Tolson and the Toledo Zoo for supporting research on captive breeding of West Indian herpetofauna. We are indebted to Amphibian Ark for improvement of facilities for *ex situ* research. Kevin Johnson and A. Cádiz reviewed first drafts of this manuscript, and their suggestions highly improved it. Kevin Zippel, R. Gagliardo, and R. A. Odum provided valuable information and training. Nils Navarro, M. Rodríguez, K. Ng, and E. Gabot helped with field work. Ariatna Linares participated in the food production and care of frogs. Michael Schmid, W. Feichtinger, C. Steinlein (University of Wuerzburg, Germany), and Y. Samyn (Belgian Focal Point to the Global Taxonomy Initiative at the Royal Belgian Institute of Natural Sciences) donated photographic equipment. Thanks to the Laboratory of Ornithology of Cornell University, particularly to G. Budney, J. Fitzpatrick, and E. Íñigo, for their help and support. Our deepest gratitude to two anonymous reviewers, K. Johnson, and R. Hill for improving the manuscript.

HERPETOCULTURE NOTES

ANURA — FROGS

***MIXOPHYES BALBUS* (Stuttering Frog). LARVAL DURATION.** *Mixophyes balbus* originally occurred from coastal far eastern Victoria to south-east Queensland, Australia, but is now rare or absent throughout much of its former range (Gillespie and Hines 1999. *In* A. Campbell [ed.], Environment of Australia, pp. 109–130. Canberra, Australian Capital Territory; Hunter and Gillespie 2011. National Recovery Plan for the Stuttering Frog *Mixophyes balbus*. Department of Sustainability and Environment, Melbourne, Victoria). In Victoria, it was known from only three locations and may now be locally extinct (Gillespie, unpubl.). The species is listed nationally as Vulnerable and a recent genetic study indicates that it may consist of two distinct clades (S. C. Donnellan, unpubl.; Hunter and Gillespie 2011, *op. cit.*).

Melbourne Zoo has maintained a captive population of *M. balbus* since 2001, when founder animals of the northern clade were collected from the Timbarra Plateau in northern New South Wales to provide material for developing captive reproductive techniques for the species. These frogs have since reproduced successfully on numerous occasions at the zoo (Banks et al. 2014. Herpetol. Rev. 45:43–49).

One spawning on 9 September 2004 comprised approximately 280–310 eggs laid in a "nest" (excavation in the gravel substrate) measuring 65 mm × 65 mm × 25 mm deep in a shallow riffle zone of the enclosure. Mean water temperature was 18°C (range 15–22°C). Tadpoles started to hatch 6–8 days after laying, and were provided with frozen endive and Sera© tropical fish flakes *ad libitum*. Tadpole tanks lacked hides, measured 360 mm × 410 mm × 310 mm (36 L), and had overflow pipes with grill covers to prevent tadpoles being flushed down the drain. Fresh water was supplied constantly to the tanks at approximately 2 L/h, and each tank had an aquarium air stone for oxygenation and water movement. Tadpoles were maintained in groups of 30–50 individuals. Tadpoles from this clutch started to metamorphose in early February 2005, and continued through to January 2006, i.e., 5–16 months after being laid.

One tadpole did not metamorphose during this period, and continued to be housed alone in a 33 L aquarium. Its husbandry remained unchanged, except that its diet was modified during the last few months of its larval life, when drops of Sera-Micron® (fish fry powder) mixed into a paste with water were supplied daily. This tadpole did not start to metamorphose until November 2009 and completed its transformation on 12 December 2009 after 5 years and 4 months as a tadpole. It was not measured at metamorphosis, but it was not significantly larger than tadpoles that metamorphosed earlier from this clutch of eggs.

It is common for frogs in the genus *Mixophyes* to have long larval lifespans, and Anstis (2002. Tadpoles of South-eastern Australia. New Holland Publ., Sydney. 281 pp.) noted that *M. balbus* typically begins to metamorphose after a minimum of 15 months in the wild. The tadpoles at the zoo commenced metamorphosis much sooner, and it is possible that this resulted from the ample food provided daily and the higher water temperatures than this species would experience in the wild; 18–23°C at the zoo versus 7–15°C on the Timbarra Plateau. Higher than normal temperatures during the larval period are known to accelerate metamorphosis (Harkey and Semlitsch 1988. Copeia 1988[4]:1001–1007; Sanuy et al. 2008. Anim. Biodivers. Conserv. 31[1]:41–46). The number of eggs laid was within the recorded range for this species of 132–550 eggs (Anstis 2002, *op. cit.*).

Anurans are well known for their phenotypic plasticity when undergoing metamorphosis, allowing many species to respond to changing conditions in their immediate environment. These include conspecific density in *Rana temporaria* (Loman 2004. Ecology 85[6]:1611–1618), temperature in *Bufo calamita* (Sanuy et al. 2008, *op. cit.*), and synergistic effects of conspecific density and ultraviolet UV-B radiation in *Limnodynastes peroni* (Mitchell et al. 2012. Conserv. Biol. 26[6]:1112–1120). These and other effects have been recognized in comparisons between spawnings rather than within one spawning, and hence do not explain why this individual *M. balbus* did not metamorphose at the same time as its siblings.

Although the last three years of this individual's life as a tadpole, with solitary housing, ample food, and no competition, may have contributed to its extended larval period, why it did not metamorphose with the rest of its siblings remains unclear. It is possible that the change in diet to the Sera-Micron©, with a higher vegetable content than fish flakes, played a role in finally initiating metamorphosis. Sera-Micron© has since been used as a standard supplementary food for all tadpoles in the zoo's collection.

I thank Angus Martin and Chris Banks for improvements to the early drafts of this manuscript.

RAELENE HOBBS, Melbourne Zoo, Herpetofauna Department, P.O. Box 74, Parkville, Victoria 3052, Australia; e-mail: rhobbs@zoo.org.au.

TESTUDINES — TURTLES

***RHINOCLEMMYS MELANOSTERNA* (Colombian Wood Turtle). LONGEVITY.** No published longevity report exists for *Rhinoclemmys melanosterna*; the record for the genus is 20 yr 5 mo for *R. pulcherrima* (Slavens and Slavens 2000; Reptiles and Amphibians in Captivity: Breeding-Longevity-Inventory. Slaveware, Seattle, Washington). On 15 December 1975, I was given a yearling (one growth annulus; maximum carapace length 107.5 mm; maximum plastron length 102 mm) *R. melanosterna* that had recently been purchased in the food market in Turbo, Antioquia, Colombia by Diderot Gicca. The turtle (a male) was maintained on a diet of trout chow and is still alive and healthy at this writing (25 September 2013), representing a minimum longevity of 37 years, 9 months. This represents the record longevity for the genus. Images of the yearling and adult are available from the author.

JOHN B. IVERSON, Department of Biology, Earlham College, Richmond, Indiana 47374, USA; e-mail: johni@earlham.edu.

SQUAMATA — SNAKES

***BOIGA IRREGULARIS* (Brown Tree Snake). CAPTIVE REPRODUCTION AND LONGEVITY.** *Boiga irregularis* is a rear-fanged, venomous colubrid native to Australia, New Guinea, the Solomon Islands, and parts of Indonesia. The biology of this species has been intensively studied due to the ecological impact that an invasive population has had on Guam (Rodda and Savidge 2007. Pac. Sci. 61:307–324). Despite this, its reproductive biology

has proven particularly elusive, with few gravid females or wild clutches observed (Savidge et al. 2007. Pac. Sci. 61:191–199). Records of captive reproduction are equally scarce, with only a few instances being recorded (Barnett 1993. Monitor: Bull. Victorian Herpetol. Soc. 5:11–14; Mathies and Miller 2003. Zoo Biol. 22:227–238). In this note, we provide new data from old records on captive reproduction, including a new maximum clutch size, the first report of double clutching and a new longevity record for this species.

On 9 October 1984 a pair of mature *B. irregularis* arrived at Taronga Zoo, Sydney, Australia, from a shipment of bananas from Tully in north Queensland. Unfortunately, there were no weights or lengths recorded for these specimens and the only subsequent mass record was on 15 February 1995, when both individuals weighed 900 g (± 50 g). The pair was housed together after their arrival at the zoo, initially in the existing reptile house until being moved to the newly built Serpentaria building on 3 April 1995.

Between 1984 and 1995, the female produced a total of eight clutches (Table 1). The first clutch of six eggs was laid 36 days after arrival, suggesting that the female was probably gravid when captured. The subsequent clutches beginning after four years in captivity were much larger, ranging from 10 to 16 eggs. The data on the lay date and clutch size for clutch 5 cannot be located, though 13 eggs from this clutch hatched on 14 February 1992. Based on incubation times for clutches 1 and 2, the estimated lay date would be mid-late November 1991. To date, the previous maximal clutch sizes recorded for this species are 12 eggs (McPhee 1979. The Observer's Book of Snakes and Lizards of Australia. Methuen of Australia, Sydney. 157 pp.), 11 eggs in Australia (Shine 1991. Copeia 1991:120–131), and 9 eggs on Guam (Savidge et al. 2007, *op. cit.*). Two of the clutches reported here exceed the largest known clutch of twelve eggs. This may possibly be related to the large mass of 900 g that the female was able to attain in captivity, as clutch size is correlated with female size in this species (Shine 1991, *op. cit.*). A previous study of 34 wild-caught female *B. irregularis* from the Wet Tropics of Queensland recorded a maximum mass of only 750 g (Trembath and Fearn 2008. Aust. J. Zool. 56:173–178).

Seven of the eight clutches were laid in November or December, indicating a regular seasonal cycle. The only exception to this was an instance of double clutching in a single activity season. In March 1992, a clutch of 11 eggs was laid four months after the previous clutch of at least 13 eggs. Although it has not been previously recorded, Savidge et al. (2007. *op. cit.*) suggested that this species may be able to produce more than one clutch per season as reproductive specimens have been recorded in all months and double clutching has been noted in its congener *B. blandingi* (Groves 1973. Int. Zoo. Yrbk. 13:106–108). This provides the first evidence of *B. irregularis* producing two clutches in a season.

Incubation was attempted on four of the eight clutches. This resulted in hatching success of 5 from 6 eggs in 1984, 9 from 12 eggs in 1988, 0 from 11 eggs in 1990 and 13 from an unknown number of eggs in 1991. Data on egg size, incubation conditions, and hatchling morphology was not available.

The female died on 7 May 1997 and the male on 16 December 2000, after 12 years 7 months and 16 years 2 months in captivity, respectively. Savidge et al. (2007, *op. cit.*) indicate that this species does not mature in the wild until 3–4 years. If they were at least 30 months of age when captured, this suggests the male and female attained the age of at least 19 and 15 years, respectively. There are no recent accurate reports on longevity in this species with the only previous published record indicating a captive lifespan of 13 years 1 month in a wild-caught specimen (Slavens and Slavens 2000. Reptiles and Amphibians in Captivity: Breeding, Longevity and Inventory. Slaveware, Seattle, Washington. 400 pp.). Thus, this note substantially increases the known longevity of this species.

Table 1. Clutches of *Boiga irregularis* laid at Taronga Zoo from a single pair of snakes. * For clutch 5, the oviposition date and clutch size are not known, though 13 snakes hatched.

Clutch	Date	Eggs laid (& hatched)
1	14 Nov 1984	6 (5 after 82 days)
2	26 Dec 1988	12 (9 after 88–92 days)
3	27 Nov 1989	12 (N/A)
4	16 Nov 1990	11 (0)
5	Nov 1991	13* (13)
6	22 Mar 1992	11 (N/A)
7	18 Nov 1992	10 (N/A)
8	5 Dec 1995	16 (N/A)

MICHAEL McFADDEN and **TERRY BOYLAN**, Herpetofauna Division, Taronga Conservation Society Australia, P.O. Box 20, Mosman, New South Wales 2088, Australia (e-mail: mmcfadden@zoo.nsw.gov.au).

***LAMPROPELTIS HOLBROOKI* (Speckled Kingsnake). LONGEVITY.** I purchased a male *Lampropeltis holbrooki* 23 April 1975 that was hatched at the Buffalo Zoological Gardens 17 February 1975. It died 18 August 2013, living 38 years, 6 months, and a day, far surpassing the record for this taxon of 14 years, 5 months, 22 days reported by the St. Louis Zoo, St. Louis, Missouri (Snider and Bowler 1992. Longevity of Reptiles and Amphibians in North American Collections. SSAR Herpetol. Circ. 21:1–40) and that for Colubridae of 33 years, 4 months reported by Craig Dible, Marina del Rey, California, USA (Snider and Bowler 1992, *op. cit.*). At death the snake measured an unremarkable 142 cm TL.

HENRY COHEN, 24 St. John's Place, Buffalo, New York 14201, USA; e-mail: hencoherp@aol.com.

***LAMPROPELTIS KNOBLOCHI* (Knobloch's Mountain Kingsnake). LONGEVITY.** An adult sexual pair of *Lampropeltis knoblochi* was obtained from a private collector 17 March 1983 (as *L. pyromelana woodini*). The female died 21 September 2008. The male died 22 June 2012 having been in my collection for 29 years, 3 months, and 5 days. Based on observed growth rates in captivity for this species, it is reasonable to assume he could have been another 3 years older. The previous longevity record for this species (as *L. p. woodini*) was 19 years and 4 days in the collection of Tom Porter (Snider and Bowler 1992. Longevity of Reptiles and Amphibians in North American Collections. SSAR Herpetol. Circ. 21:1–40). A male *L. p. pyromelana* living 22 years, 5 months, 10 days was reported by the Pittsburgh Zoo, Pittsburgh, Pennsylvania, USA (Snider and Bowler 1992, *op. cit.*).

HENRY COHEN, 24 St. John's Place, Buffalo, New York 14201, USA; e-mail: hencoherp@aol.com.

CONSERVATION

This section provides a platform to showcase innovative conservation projects, partnerships in achieving conservation and management objectives, and conservation success stories or lessons learned, and to bridge the gap between science and management. Subjects appropriate for this section include the following:

- *In-situ* conservation programs, particularly those involving local communities and governments
- *Ex-situ* conservation programs and success stories, or lessons learned
- Habitat protection or species appreciation and protection via ecotourism, education, and outreach
- Proactive and multi-partner efforts to improve conservation policies or actions, or to increase public awareness of conservation issues
- Point-counterpoint essays on hot topics in herpetofaunal conservation

Manuscripts, ideas, or questions for consideration should be directed to Conservation Section Editor, Priya Nanjappa (pnanjappa@fishwildlife.org). All manuscripts will undergo external peer review. For detailed instructions on manuscript preparation, please consult the SSAR web page at: http://www.ssarherps.org/pages/HRinfo.php. For authors whose native language is not English and who might require assistance with manuscript preparation, we invite you to consult SSAR's Presubmission Manuscript Review service: http://www.ssarherps.org/page/presub.php.

Herpetological Review, 2014, 45(1), 62–65.

The Reticulated Flatwoods Salamander (*Ambystoma bishopi*) is among North America's most imperiled salamanders. The species is federally listed as endangered (United States Fish and Wildlife Service [USFWS] 2009) and is listed as "vulnerable" by the International Union for the Conservation of Nature (IUCN). Little is known regarding the basic natural history for the species (Jones et al. 2012). An inhabitant of longleaf pine flatwoods habitat, the species once occurred in southwestern Georgia, southeastern Alabama, and across the Florida panhandle. The only remaining breeding populations that are known are located in the Florida panhandle, largely occurring on Eglin Air Force Base. The species has not been observed in Georgia since 2001 (J. Jensen, pers. comm.) and has not been seen in Alabama since 1986 (J. Godwin and S. Graham, pers. comm.). Primary factors behind the decline are habitat alteration, fragmentation, and insufficient hydroperiod in breeding sites with isolated breeding populations being at higher risk of extirpation without possibility of recolonization (USFWS 2009).

In the fall/winter of 2011–12, drought in the Florida panhandle prevented the filling of ephemeral breeding ponds used by *Ambystoma bishopi* on Eglin Air Force Base. The salamanders deposit eggs along what will be the bottom of the ponds, but typically do so before heavy seasonal rains cause the ponds to fill with water (Anderson and Williamson 1976; Hill 2013). As the ponds fill, the eggs hatch and the aquatic larvae develop, if given enough time before the ponds dry out again. Late into the breeding season of 2011–12, the ponds had not filled with water, and the eggs had remained dry through their anticipated hatch dates. A USFWS official made the call to declare the eggs as "salvage material." The declaration made the eggs available for collection in an attempt to hatch and rear the larvae. Collaborators at Virginia Tech requested the development of a protocol for rearing the federally endangered ambystomatid from the amphibian conservation

program at the Atlanta Botanical Garden (the Garden). The Garden sent one of the authors (DBF) to Florida to collect eggs and bring them back to the facilities in Atlanta. Because this species and its sister species, the Frosted Flatwoods Salamander (*Ambystoma cingulatum*) are both declining, one of our primary goals was to make our methods for collecting eggs, hatching larvae, and rearing larvae through metamorphosis readily available.

Egg collection and transport.—In early January 2012, eggs were collected from Eglin Air Force Base under the authority of the USFWS. Eggs are deposited as small groups (from 1–17 eggs have been observed), and we removed the eggs by taking a divot of earth from around each group of eggs that was roughly 5–10 cm out from the edge of the group of eggs. We then placed the excavated divot into small plastic boxes (Fig. 1). By using this approach the eggs were not physically removed from the substrate, did not change orientation and overall disturbance was minimized. The plastic boxes were then stacked inside of portable plastic coolers for transport from Florida to the Garden.

Housing eggs and larvae.—At the Garden, each divot was placed into a larger plastic shoe box. By gradually raising water levels in the plastic shoe boxes, up to a point where the water was just touching the eggs, we were able to hatch the eggs. Water used for this process had been prepared two weeks prior with peat moss pillows to lower the pH of the water from 7 to 5.8, which is near the natural pH for breeding wetlands (Palis 1996). The water had also been carbon filtered prior to pH adjustment to remove potentially harmful chemicals and metals. The eggs were maintained in a conservation greenhouse (used for cultivation of endangered plants from the southeastern United States) with natural lighting and temperature regimes. Mean air temperature ranged from 10°C to 23°C for the larval period (Fig. 2). Once larvae hatch they need to be isolated and placed into individual plastic containers to avoid conspecific aggression. Isolation reduces the risk of cannibalism and spread of disease. Plastic containers of roughly 1L in volume are sufficient. A small plastic plant pot was added to the enclosure to provide cover for the developing larvae. The containers with the developing larvae inside of them were maintained in the same greenhouse as described above.

Larval development in captivity proceeded from hatching in January until May 2012 (roughly 18 weeks), therefore the decision was made to lower the water levels on the developing salamander larvae to 1 cm total depth. It was noted that the larval period was taking longer in captivity than in the wild, where Palis (1995) documented larval development of flatwoods salamanders to last from between 11–18 weeks. Within one week of lowering the water level, three larvae (Fig. 3) started to change color and pattern. The stripes began to fade and a darker gray color replaced the brown coloration of earlier larval stages; furthermore, at metamorphosis pale white or silver spots began to develop over the dorsum of the salamanders (Fig. 4). These three individuals metamorphosed in the third week of May 2012, but one individual drowned in the process. At this point, sphagnum moss was added to the containers to provide metamorphosing salamanders additional substrate on which to exit the water. We still had roughly 15 larvae approaching metamorphosis. Metamorphosed larvae have a gray base coloration with metallic colored dots all over the dorsum. The dots range from a faint blue color to white or silver (Fig. 4). When early metamorphs have blue dots, they fade to white with time.

Feeding larvae and metamorphs.—When larvae hatched they were approximately 1–1.5 cm total length (Fig. 3). Owing to the season, there were no abundant micro-crustaceans available to Garden staff to feed the salamanders; however, we placed frozen fish foods into a blender and we introduced the slurry to larval salamanders. The specific frozen foods used were as follows: San Francisco Bay Brand, Inc. frozen bloodworms ("red dipteran larvae") and glassworms ("white dipteran larvae"), and Bio-Pure brand frozen *Daphnia* and frozen brine shrimp. Hatchling salamanders could be seen eating the viscous mixture of thawed and blended foods. Shortly thereafter, live "black worms" (*Tubifex tubifex*) were purchased from a commercial dealer. We blended and fed the results to the salamanders, which was also accepted as a food item. To diversify the diet, we also fed larval salamanders live *Daphnia magna* that were purchased from Ward's Natural Science Company and another species of *Daphnia* provided by Conservation Fisheries Inc. (Knoxville, Tennessee).

One concern about feeding salamanders following metamorphosis came from J. Mendelson (Zoo Atlanta) who previously attempted to rear several *Ambystoma cingulatum* from the larval stage. While there were no problems feeding and rearing the larvae, following metamorphosis the salamanders would not eat and ultimately died. Taking this into consideration we fed late stage larvae hatchling earthworms (*Eisenia hortensis*) as well as larger earthworms cut to approximately 1 mm pieces from worm colonies at the Garden. After metamorphosis, the same hatchling earthworms were offered as food. Introducing this food item in the larval stage ensured that a familiar food would be available and would hopefully appeal to the salamanders through their metamorphic period. *Ambystoma bishopi* are not known to go through paedomorphosis, like some other ambystomatids, so all individuals go through metamorphosis into the terrestrial life stage. To date, we have not had a problem with salamanders accepting the small earthworms post-metamorphosis. In addition, the salamanders have accepted termites (*Reticulitermes* sp.) and cultured terrestrial isopods (*Trichorhina tomentosa*).

European night crawlers (*Eisenia hortensis*) are known in the aquarium trade and at fishing bait shops as "Euro Drift Worms." They are easily cultured and are a relatively small species of night crawler. One benefit to culturing them is that every size class is available from a colony, and small amphibians can be given newly hatched worms as they are roughly 3–6 mm in total length. Culturing *E. hortensis* involves the use of Care Fresh® pet bedding (use the uncolored version). The media is widely available through the pet industry and online. The material is acceptable to Institutional Animal Care and Use Committees because it is laboratory sterile and does not contain dirt (a consideration for any university-based live animal research program dealing with fossorial amphibians). We used the version of the product that has no added dyes or colors. The material is placed into a bucket with clean, carbon filtered water. Once the paper is saturated, it is placed in a large fish net and gently squeezed to remove excess water. The damp media is then added to plastic tubs to a depth of 12–20 cm. The plastic tub must have a tightly fitting lid. Starter cultures of 50–100 worms are added to the media and maintained in cool locations with daytime temperatures no greater than 23.8°C and night time temperatures no lower than 10°C. Any commercial earthworm food can be used to feed the worms weekly as well as store brand white loaf bread. Turn the substrate over one or two times a month to free trapped pockets of gas. As the media decomposes, add new media. The culture will smell with time as gases from decomposition build up, which is normal. Drain fluids from the bottom of the culture as they develop. One advantage to using cultured earthworms as food items is

FIG. 1. Small divots of substrate were excavated around *Ambystoma bishopi* eggs to reduce physical damage by the egg collection process and were then placed into Tupperware® plastic boxes to limit movement and damage to the eggs during transportation to Atlanta Botanical Garden for rearing.

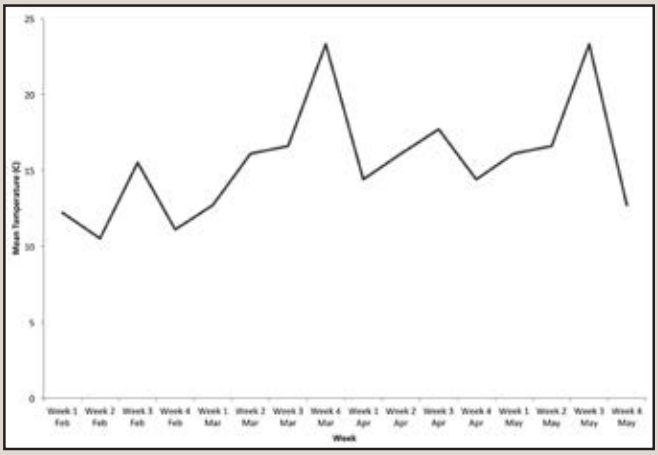

FIG. 2. Mean air temperatures in the greenhouse at the Atlanta Botanical Garden where *Ambystoma bishopi* eggs were hydrated, hatched, and reared from January–May 2012.

FIG. 3. At one hour post-hatch, larval *Ambystoma bishopi* do not have hind limbs and only have partially developed forelimbs and digits.

FIG. 4. A newly metamorphosed *Ambystoma bishopi* demonstrates the mix of larval and juvenile pattern. The body of the animal is now dominated by black and white, whereas the larvae have brown stripes on a tan base coloration; however, the stripes can still be seen in this metamorph, a character that will be lost three to four weeks post-metamorphosis.

FIG. 5. Mid- and late-stage *Ambystoma bishopi* larvae have a well-defined pattern, fully developed hind limbs, and long digits.

that they can also serve as a delivery system for additional vitamins and minerals to captive amphibians. Adult earthworms can be injected with a small gage hypodermic needle with a slurry of amphibian vitamins. We use Repashy Superfoods "Supervite" and dissolve several micrograms of the vitamins in one ounce of filtered water. The vitamin laden worms are then offered directly to the salamanders as food items.

Terrestrial "dwarf white" isopods (*Trichorhina tomentosa*) are readily available and are also relatively easy to culture. Their small size makes them ideal food items for small amphibians, particularly metamorphic animals. E. Kowalski (Philadelphia Zoo) provided the Garden with this procedure for rearing *T. tomentosa*. Ground coconut shell (available online and through the pet trade) is mixed with ground leaves at a ratio of two to one respectively. Oak, maple, ash, or fruit tree leaves are all acceptable for use. Dead leaves are collected below a tree and carefully rinsed with carbon filtered water. The leaves are dried and cut with scissors to slices roughly 4 cm in length and 1 cm in width. These sliced leaves are then thoroughly mixed into the ground coconut. The material is then misted with carbon filtered water until it clumps and is damp to the touch. Isopods can be observed actively crawling around

on the substrate and the food that is offered. One to two cups of the material is added to a plastic deli cup (0.47 L) with a ventilated lid. Isopods are fed flake fish food once or twice a week (sparingly) and a slice of potato is placed into the culture once a month. The potato slices (can use squash or carrots) will have clusters of isopods on them and they can be harvested on this or a small piece of cardboard, on which the isopods will also cluster.

Discussion.—The Reticulated Flatwoods Salamander is experiencing a range-wide decline (USFWS 2009). While localized populations do remain, a lack of dispersal ability or the need for restoration of wetlands (Gorman et al. 2009) and uplands at formerly occupied sites may prevent recolonization. Efforts are underway to restore habitat; however, these efforts take considerable time (Gorman et al. 2013). With the breeding range reduced to a relatively small area, prolonged regional drought, especially in conjunction with anthropogenic alterations of local hydrology, could cause extirpation. These issues highlight the need to develop captive rearing protocols and assurance colonies that can later be used as a source population for restored sites. We have outlined procedures to collect eggs, hatch larvae, and rear larvae through metamorphosis that can be used to develop these assurance colonies. The development of these colonies can then be used as a tool to intervene in the decline, should that measure be called for by the USFWS. Very little is known about dispersal of flatwoods salamanders (see Ashton and Ashton 2005), and a better understanding of genetic variation among local populations is needed before release of captive animals proceeds. Assurance colonies should be initiated sooner rather than later, however, while individuals can still be obtained from the wild. The development of a captive breeding protocol is the next step with our project, and we will publish our results in an effort to disseminate whatever techniques we are able to produce. The development of captive assurance colonies may provide a tool for wildlife biologists to develop methods with which to deal with potential disease and reintroduction programs.

The developmental period for the salamanders in captivity may have lasted longer than those in the wild (11–18 weeks; Palis 1995). One potential cause for the longer captive developmental period might have been a consistent water level and water temperatures. Water had been added to the containers holding the larvae throughout the developmental process to replace loss via evaporation (maintained at approximately 8 cm depth). Without decreasing water levels, larvae may not metamorphose as quickly as in drying ponds in the wild, though deep sections of natural ponds still contained larvae after metamorphs had been observed, so a longer larval stage may not be cause for concern. Furthermore, larger size at metamorphosis has been linked to higher post-metamorphic survival (Scott 1994) and reproductive fitness (Scott 1994; Semlitsch 1988) in closely related salamanders, so a longer larval stage may be desirable, assuming growth is continuing. Prior to metamorphosis, larvae were approximately 3–4 cm total length (Fig. 5).

Acknowledgments.—We thank Eglin Air Force Base, especially Kathy Gault and Bruce Hagedorn, for logistical support, and the assistance of Brandon Rincon, Steve Goodman, John Himes, and Annamarie Saenger with detection and collection of eggs in the field. Conservation Fisheries Inc. (Knoxville, Tennessee) kindly supplied cultured freshwater amphipods to use as food with early stage salamander larvae.

The second largest (743,380 km^2) tropical island (after New Guinea), Borneo straddles the equator between coordinates 04°S–07°N and 10–119°E (Fig. 1). Croizat (1958) described Borneo as a geological composite, and the island sits on the eastern margin of the Sunda Shelf, a Laurasian continental plate. Until three decades ago, the island comprised vast swaths of tropical forest, and a diversity of forest types and contrasting habitats, ranging from extensive lowland dipterocarp forests, significant areas of blackwater swamps, and high mountains. The seas around Borneo are generally shallow (< 200 m), contributing to faunal similarities with the faunas of Sumatra (to the west), Java (to the south), and Peninsular Malaysia (in the north), all areas lying on the Sunda Shelf. Exceptionally deep waters (> 2000 m) of the Makassar Strait, to the east of Borneo, separate that island from Sulawesi, which lies on the Sahul Shelf. Wallace's Line, demarcating the Oriental fauna from that of Australasia, is positioned across these deep-water straits

Apart from contemporary habitat conditions, past climates and land connections are linked to present diversity. During the glaciation events of the Pleistocene, sea levels in the northeast approached 140 m below present level in the Sulu Sea (Linsley 1996), while to the north, the north Sunda Shelf was -116 to -114 m (Hanebuth et al. 2000) when the Sundaland formed a gigantic landmass (Molengraaff 1921; Morley and Flenley 1987). Generalized reconstructions of the Southeast Asian archipelago during the Pleistocene have been shown by Voris (2000). Climate change coinciding with this last glacial maxima, ca. 23,000–18,000 years before present, brought in more dry, cool, as well as seasonal environments (Flenley 1997; Earl of Cranbrook 2000), and presumably permitted the movement of biota to and from Borneo (Ashton 1972; Sartono 1973).

The current climate of Borneo is characterized by high, equitable temperatures and heavy rainfall spread throughout the year. The relatively wetter periods are during the Northeast Monsoons (November to April), although the Southwest Monsoons (April to August) bring some rainfall. Daytime temperatures in most low-lying areas are 30–32°C, and humidity is typically above 70%; while in the highlands, such as the 4095 m Gunung Kinabalu, temperatures can reach freezing point at the summit. Annual precipitation is 4,000–5,000 mm. However, localized effects of geomorphological features, including mountain massifs and bays, have significant effects on weather conditions and on the local biotas within the island.

Three independent countries are situated on Borneo, their boundaries demarcated by either high mountains or large river basins, the largest being Indonesia (539,460 km^2, divided into four provinces of Kalimantan), with other significant portions being Malaysia (divided into the states of Sabah, 73,710 km^2 and Sarawak, 124,450 km^2), and the smallest entity is the Sultanate of Brunei Darussalam (5,760 km^2). Forestry practices differ within these political units, influencing the extent and quality of their natural vegetation.

FIG. 1. Digital elevation model map of Borneo.

Borneo's size, location, and geological history have contributed to the high amphibian species diversity (see Table 1). New species continue to be described annually with every significant collecting effort even in well-sampled sites, or when larger species complexes are systematically revisited, particularly using tools of molecular analyses. Amphibians, for their dual requirement of both clean water and forest cover, are surrogates of tropical biodiversity.

Studies of Borneo's amphibian fauna commenced with early European visitors, primarily the British (in northern and western Borneo) and the Dutch (in the southern parts of the island), who were often explorers and natural historians (Das 2004). The frog fauna of the island is currently accessible to a lay audience via the field guide of Inger and Stuebing (2005), now in its second edition. It draws upon the substantial research of these authors, spanning over half a century, that earlier resulted in the monographic revisionary work of Inger (1966).

Of the 178 amphibian species now known from Borneo, 130 (or 73%) are endemic to the island. An additional 43 species are distributed across Sundaland (including the Malay Peninsula, Sumatra, Java, and Bali), but not beyond, these being referred

to as Indo-Malayan elements in the fauna of the island. Among them are several whose extra-Bornean distribution is only peripheral (*Limnonectes palavanensis* and *Microhyla petrigena*). Autochthonous genera on Borneo include *Borneophrys, Leptobrachella, Meristogenys,* and *Sabahphrynus*. Other more widespread Sundan lineages show major radiations here, include *Ansonia* (12 species), *Kalophrynus* (10 species), *Leptobrachium* (six species), *Leptolalax* (seven species), *Pelophryne* (eight species), *Philautus* (19 species), and *Rhacophorus* (15 species). Several essentially Indo-Chinese elements identified on Borneo, possibly relictual from the time of land connection with the Asian mainland, include *Feihyla*, *Ingerana*, and *Odorrana*. Adding to the frog fauna are several species that are human commensals, and suspected to have arrived in the past century, mostly inadvertently with plants and other agricultural products (including *Duttaphrynus melanostictus* and *Kaloula pulchra*), and one is an escapee from frog farms (*Hoplobatrachus rugulosus*).

The most recent assessment of the world's amphibians paints a bleak picture for the Bornean amphibian fauna (see Table 2; IUCN 2013; http://www.iucnredlist.org/). A total of 27 species are classified as NE (Not Evaluated). Of those whose conservation status has been assessed, 15 are DD (Data Deficient), 54 LC (Least Concern), 40 are NT (Near Threatened), 30 are VU (Vulnerable), nine EN (Endangered), and three CR (Critically Endangered). Belonging to the most threatened categories are three species with rather restricted ranges, two of which were described only in the last decade— *Pelophryne linanitensis* and *P. murudensis* (from Sarawak) and *Leptobrachella palmata* (from Sabah). No active conservation measures have been directed thus far to assure their continued survival. Excluding those in the NE, DD, and LC categories, there are 82 threatened species, representing 46%, or nearly half the known amphibian fauna of the island. These figures are, of course, conservative estimates, as species complexes (or biological species nested within morphologically similar species complexes) exist within a number of species that are currently categorized as Least Concern (including, among others, *Limnonectes palavanensis*, *Occidozyga sumatrana, Leptobrachium abbotti*, *L. montanum*, *Megophrys nasuta*, *Chaperina fusca, Kalophrynus heterochirus, K. pleurostigma, Odorrana hosii*, *Kurixalus appendiculatus*, *Philautus petersi*, *Polypedates macrotis*, *Rhacophorus cyanopunctatus,* and *R. pardalis*). These indicate insufficiency in current knowledge of Bornean frogs, and a need for further research on a diverse series of disciplines, from taxonomy and systematics, to ecology, ethology, and distribution.

Rates of deforestation are high in Borneo (Primack and Hall 1992; Bryan et al. 2013); the major driver of deforestation is logging for hardwoods and clearing of land for oil-palm plantations and urbanization. Such landscape change has been instrumental in population fragmentation and extinctions. One recent study reported the persistence of many amphibian species, including Bornean endemics, in secondary forests, but not in plantation forests (Gillespie et al. 2012). On the Indonesian portion of Borneo, an ambitious project of settling people from densely populated islands of Java and Madura into Kalimantan (Fearnside 1997) implies clearing of more forest land for agriculture and settlement. During the dry season, many forests are prone to fire, accidentally started, or used by settlers to clear vegetation to prepare the land for agriculture (swidden cultivation). Other factors that threaten local amphibians are harvest for food and introduction of exotic species from the food or pet trade, which may, on one hand, compete with local amphibians, and on the other, introduce deadly diseases. At least one species (*Hoplobatrachus rugulosus*) is introduced on Borneo, presumably having escaped from frog farms. In the Malay Peninsula, two additional exotic species of frogs can claim residency—the American *Lithobates catesbeianus* and the Chinese *Hylarana guentheri*. The large number of exotic amphibian species offered for sale in local petshops in towns of Sarawak and Sabah (including North American, European, and African frog and salamander species) is a further cause for concern, as several (including *Ceratophrys* spp. and *Xenopus laevis*) have been linked to the deadly fungal pathogen, *Batrachochytrium dendrobatidis* (Phylum Chytridiomycota), often abbreviated as *Bd*.

The Bornean Frog Race is celebrated on the last weekend of April. Since 2012, two editions have been held. The event coincides with the annual "Save the Frogs Day" (www.savethefrogs.com/day), a global action celebrated via 270 events in over 30 countries, to highlight conservation issues facing the world's amphibians. The Race is organized by the students and staff of the Institute of Biodiversity and Environmental Conservation (IBEC) of the Universiti Malaysia Sarawak (UNIMAS). UNIMAS is a federal body within the autonomous Malaysian state of Sarawak, with one of its research areas being tropical biodiversity. This area of research is appropriate given the university's strategic location in the heart of a Southeast Asian biodiversity hotspot. The first Bornean Frog Race was held to coincide with UNIMAS's 20th anniversary, at the Permai Rainforest Resort, on the evening of 28 April 2012. The event comprised exhibitions, talks, and a race to document amphibians in Gunung Santubong National Park. No inventories of this mountain have been published before, although the massif has a long history of zoological explorations, starting with Alfred Russel Wallace (1823–1913), who collected on Santubong in 1855, and during his stay at the village in the foothills, wrote his most famous paper, entitled "On the Law Which has Regulated the Introduction of New Species." The Race was publicized through IBEC's website (http://www.ibec.unimas.my/save-the-frogs-day-2012.html), the Raffles Museum website (http://rafflesmuseum.wordpress.com/2012/04/23/the-bornean-frog-race-2012/), and through Facebook (http://www.facebook.com/TheBorneanFrogRace2012). An exhibit pertaining to amphibian diversity, comprising photographs of frogs, an exhibition of books on frogs, and a display of amphibians depicted in postage stamps of the world. A special philatelic sheet was brought out on the date, in association with Pos Malaysia, under the SetemKu program, featuring the Bornean Rainbow Toad (*Ansonia latidisca*), the subject of a natural history talk given by UNIMAS graduate student, Ong Jia Jet. This is one of the 10 "Lost Frogs" in the list by Conservation International, and considerable media publicity was received upon its rediscovery (Pui et al. 2011). A computer displayed images and played calls of frogs of the world. The Race was attended by 41 participants (many of whom were students from UNIMAS, in addition to members of the Malaysian Nature Society, and staff of the Sarawak Forest Department and Sarawak Forestry Corporation). Participants had about 120 minutes to go up a trail on Gunung Santubong and photographically document amphibians.

Three prizes were awarded for each of the following categories: a) the three best amphibian photos taken; b) the rarest amphibian found; and c) the most species found. Two extra prizes for the Judge's Special Award were given to: a) the youngest participant, and b) the most enthusiastic participant. The main prizes included natural history books, donated by Datuk Chan Chew Lun, proprietor, Natural History Publications (Borneo)

Table 1. Checklist of the amphibians of Borneo, current as of 21 October 2013, annotated with the current IUCN Red List status (IUCN 2013). Abbreviations include: NE = Not Evaluated; DD = Data Deficient; LC = Least Concern; NT = Near Threatened; VU = Vulnerable; EN = Endangered; and CR = Critically Endangered. One introduced species has been indicated with an asterisk.

Sdn Bhd., based in Kota Kinabalu. Other prizes were donated by UNIMAS and organizers of the Race, including book vouchers from a leading book shop in Kuching. The event was covered by the local news media (*The Star, Kuching, Borneo Post*, and *Utusan Malaysia*), as well as magazines specializing in tourism and travel.

The second Bornean Frog Race was held on 27 April 2013, and was a larger event (Fig. 2). The venue was Kubah National Park, a part of the Matang Range, close to the city of Kuching. The range is home to nearly 60 species of amphibians (Das et al. 2007), with several undescribed. This version of the Race was organized in collaboration with the Sarawak Forestry Corporation (SFC), towards the end of the Kubah Week celebrations (a week-long education and fun event which included guided tours covering flora, fauna, and heritage walks, to collection sites of Victorian naturalists—Odoardo Beccari [1843–1920] and Wallace). The Race was attended by over a hundred participants and accompanying persons, which was the limit set by the organizers, and comprised a day-long series of events, starting with a parallel junior education program (led by Ramlah Zainuddin,

Senior Lecturer at the Department of Zoology, UNIMAS) at the Matang Wildlife Centre, where school children from Kuching learned about frogs, tadpoles, and their respective habitats within a wider context of conservation. Talks on amphibians and an amphibian photography workshop were organized at Kubah National Park for participants. The workshop was led by natural history and outdoors photographers, Hans Hazebroek and Ch'ien Lee. An exhibit room with items related to frogs was set up (Fig. 3). These included amphibian books and scientific papers, including an extensive section on works for children, amphibian toys, stamps, coins, postcards, stickers, stationary, fridge magnets, terrarium of live frogs, etc. Special posters were prepared for the Race, one showing frogs on stamps of the world (also reproduced as a postcard; see Fig. 4), another on all the amphibians recorded from Kubah National Park and the Matang Range, the latter reproduced in an A4 format for participants to use as a field guide during the Race. A Saint John's Ambulance, along with four paramedics, were on standby for any medical emergency that might occur during such events (fortunately, their services were not required).

The main prizes—books and frog sculptures—were donated by Datuk Chan Chew Lun of Natural History Publications (Borneo), Sdn Bhd. Additional prizes were donated by Paul McNamee (a watercolor of Wallace's Flying Frog; Fig. 5) and Samuel

FIG. 7. Participants prepare for the Race (April 2013).

Shonleben (a BBC DVD). Stephen Antang, Wildlife Warden of Kubah National Park, gave a welcoming speech to participants, and also described the Park and its trail systems. Andrew Alek Tuen, Director, IBEC, gave the keynote address, and Indraneil Das gave a brief talk on the beauty and diversity of amphibians, followed by the release of two batrachological items: the official Borneo Frog Race 2013 stamps, released under the Pos Malaysia SetemKu program (Fig. 6) and a demo version of an app for smartphones entitled "Frogs of Kubah." A perspective speech "Why I love frogs" was given by Datuk Chan Chew Lun, followed by the screening of BBC documentary from "Land Invaders" from the "Life in Cold Blood" series (with permission from Sir David Attenborough). The final briefing before dinner was on safety issues by Hans Breuer, friend of IBEC.

FIG. 8. Hans Hazebroek returning to the registration desk after completing the Race.

FIG. 9. Participants and volunteers of the Frog Race 2013 showing "Save the Frogs" poster.

Following an early dinner, served at the cafeteria of the newly opened Interpretation Centre of Kubah National Park, the rules of the Race were laid out by IBEC graduate students, Pui Yong Min and Ong Jia Jet (including time limit, safety issues, and ways to reduce impact on the native fauna and vegetation). Flag-off to the Bornean Frog Race was at 1830 h (Fig. 7), at the head of the Summit Trail. Headlamps and flashlights, as well as the occasional camera light, were seen bobbing up the trail for the next few minutes, until all participants disappeared up the trail in the direction of the Frog Pond, a 45-minute brisk walk along the Trail. Before 2100 h, when the long whistle went out to announce the end of the Race, the participants started drifting back to the registration desk (Figs. 8–9), recording their return and proceeding to one of 10 desks equipped with laptops to download their photographic entries. Thereafter, participants drifted into the lecture theatre, supper in hand, to hear the special talk of the day by Ulmar Grafe, of Universiti Brunei Darussalam (advisor to Stephen Spielberg for the film *Jurassic Park*), "Behaviour and Ecology of Amphibians on Borneo: Foot-flagging, Ultrasound Communication and Species Diversity," the subjects of his life-long research on the ecology and behavior of tropical frogs.

FIG. 10–11. Certificates for the Bornean Frog Race 2013.

Judging of photographic entries and other categories followed, and at 2330 h, the winners were announced in the three categories, as in the previous year. The certificates were in several attractive designs, created by Pui Yong Min (Figs. 10–11). Participation certificates were distributed and after concluding speeches by Andrew Alek Tuen and Oswald Braken Tissen of SFC, the Race came to an end just after midnight.

Several participants overnighted at one of the several chalets of the Park, while others returned the next morning, by 1000 h, before the arrival of Datuk Amar Abg Hj Abdul Rahman Zohari Bin Tun Datuk Abg Hj Openg, Minister of Housing and Minister of Tourism. After the welcoming address by Datu Hj Ali Yusop, Managing Director/CEO of Sarawak Forestry, Abdul Rahman Zohari presented some of the prizes, while others were distributed by the Conference Organizers (Figs. 12–13).

The Bornean Frog Race brings to the fore the great beauty and diversity of amphibians and their larval stages to the general public of Sarawak and Malaysia, as perhaps never before. At the same time, it emphasizes the need for their conservation, via the take home messages, given through talks, exhibits, films, as well as signage, such as 'The Dip', where participants were encouraged to dip their shoes into a tub of potassium permanganate, a solution for removing the deadly *Bd* chytrid fungus that is now linked to amphibian declines worldwide. Exposing the general public, particularly the urbanites of Kuching to the sights and sounds of a rainforest by night, and showcasing the diversity of amphibians and other life at one of Sarawak's less well-known national parks, in a convivial atmosphere, and providing educational material made the event appreciated by the participants. Many came with their entire families. The interest shown by participants (one of whom came all the way from India, another from the eastern Sarawak town of Miri, to take part in this half-day event) and the media is gratifying, and we hope to have a more eventful program in 2014, within Sarawak Government's Ministry of Tourism's Calendar of Events.

Acknowledgments.—We are grateful to UNIMAS for supporting the Bornean Frog Race 2012 under its 20th Anniversary celebrations activities, and a Shell Chair grant for support of the Bornean Frog Race 2013. Our partners for these two versions of the Race were the Permai Rainforest Resort and the Sarawak Forestry Corporation, respectively, and we are grateful to the management of both these organizations, including Rahim Bugo, Oswald Braken Tissen, Rambli Ahmed, and Mohd Taha bin Wahab, and their ground staff. At Kubah and Matang, we are grateful to Stephen Antang and Siali Aban, respectively, for various favors, especially, making their facilities available for the Race. We are grateful to the Controller of National Parks and Nature Reserves, Sarawak Forest Department, for waiver of entrance fees to the Park, and for the provision of overnight accommodation at Kubah. We appreciate the interest in the Race shown by Datu Ik Pahon and Diana Corazon Blikau, Ministry of Tourism, Sarawak State Government and Samuel Chong, Straits Central Travel and Tours. We thank Ramlah Zainuddin for making herself available as the Special Guest in 2012, and for organizing the Junior Education Program in 2013, and Ulmar Grafe, our Special Guest in 2013, for his inspiring talk on amphibian

FIG. 12. The winning image for the first prize for the Bornean Frog Race 2013 by Philip Chen Zhao Ching.

FIG. 13. Some of the winners of the Bornean Frog Race 2013.

behavior and ecology. For helping out with the events at the Borneo Frog Race 2013, we thank Hans Breuer, Hans Hazebroek, and Ch'ien Lee. We appreciate the generosity of Datuk Chan Chew Lun, of Natural History Publications (Borneo) Sdn Bhd, in sponsoring the prizes of books and frog sculptures. Other gifts were donated by Samuel Shonlenen and Paul McNamee, and Members of the Frog Race Organizing Committee. We are indebted to Sir David Attenborough and the BBC for permission to show an episode from 'Life in Cold Blood,' and to Plaza Merdeka for being the venue sponsor for our outreach and promotional activities in Kuching. Alexander Haas has been our collaborator on amphibian research for the past decade, and during this period, our inventory of the amphibians of the Matang Range was performed. Our thanks are due to him, and to Volkswagen Stiftung for a research grant (1/79 405).

A large number of volunteers made these events possible. For the 2012 Race, we thank: Jenny Ngeian, Anna Norliza binti Zulkifli, Cindy Peter, Rahah Mohd Yakup, Pang Sing Tyan, Koay Yee Chen, Jessica Chai Swin Joe, Ik Wadell Ik Pahon, and Meri binti Sabas. In 2013, we were assisted by: Meri Sabas, Rahah binti Mohd. Yakup, Mohd. Hasri Al Hafiz bin Haba, Sauyah binti Su'aut, Pang Sing Tyan, Ik Wadell Ik Pahon, Siti Nor Baizurah binti Chang, Khatijah binti Ismail, Erdiana Odan, Luisa Duya, Lou Wei Cheong, Ogary Kishen Migas, Cecilia Emang, and Matthew anak Jenang.

Finally, we thank the participants of the Bornean Frog Race 2012 and 2013, for their enthusiastic response to these events.

Massasaugas, Michigan, and the American Origins of Snakebite Therapy

One day in the Fall of 1886, Joseph B. Steere, a professor of zoology at the University of Michigan and curator of its museum, collected half a dozen Massasaugas (*Sistrurus catenatus*) in a corner of a large tamarack swamp just south of Ann Arbor that came to be known as "Steere's Swamp." He brought them to the university campus in a gunnysack—agitated and "rattling"—and to a dingy, cramped laboratory located beneath an amphitheater in the Medical Building (Fig. 1). Waiting for him was Henry Sewall (Fig. 2), professor of physiology, and his student assistant, Frederick Novy. As Novy later recorded about that small room, "you wouldn't use it for a dog house." Steere entered the lab and released the rattlesnakes onto the floor. Sewall soon began a series of simple but elegant experiments with some of these snakes. These tests required just six months to complete and resulted in an 8-page paper that was to provide the immunological foundation on which snakebite antiserums were produced by others. The methodological procedures that Sewall pioneered have also been used to create the diphtheria antitoxin, an event that resulted in Nobel Prizes for its two discoverers. Yet despite the importance of Sewall's fundamental contribution to snakebite therapy, he received little public attention for it at the time and even today his seminal work is underappreciated.

Henry Sewall (1855–1936)

Sewall was born the son of a Methodist minister in Winchester, Virginia, and educated at Wesleyan University (B.S. 1876) and Johns Hopkins University (Ph.D. 1879), but this resumé does not hint at his very special training in physiology. (For Sewall's biography, see Webb and Powell 1946; also Sabin 1937.) Sewall's Ph.D. was the first one awarded in physiology in the United States. His supervisor, H. Newell Martin (Fig. 3), one of the world's leading physiologists, had been trained in London primarily by Michael Foster, England's leading teacher of practical, that is, experimental, physiology and an associate of, and successor to, Thomas Huxley as professor at the Royal Institution (Hawgood 2008). Indeed, Martin had once been a pupil of Huxley's. After earning his doctor's degree in Baltimore, Sewall went to Europe for a year of additional training in physiology with Willy Kühne in Heidelberg, Carl Ludwig in Leipzig, and with Foster himself, by this time at Cambridge. Ludwig was then regarded as the greatest teacher of physiology in the world. On his return to the USA in 1880, Sewall joined the biology staff at Johns Hopkins. In 1882, he was appointed professor of physiology at Michigan where he conducted his classic work on the action of the nerves of the mammalian heart. Early in 1885, Sewall developed symptoms of tuberculosis, a disease that had plagued his family for generations. Perhaps stimulated by his own affliction but possibly also by the then-recent discoveries in France by Louis Pasteur of immunizations to anthrax and rabies, he turned his attention to immunology and to the rattlesnake as a possible model for the development of antitoxins in general.

Details of the Experiments

Sewall and Novy needed to obtain some venom, which they accomplished by restraining individual snakes by the neck with a loop fixed at the end of a stick. The snakes were then forced to deposit venom at the edge of a porcelain plate. On at least one occasion, a snake broke loose from the loop, which sent Sewall and Novy scampering up onto the lab furniture for a while until they could decide how to recapture it. They were eventually able to obtain a total of six small drops of venom from three snakes. It is astonishing to recall that all of Sewall's classic experiments with snakes were conducted with such a small amount of original material. They diluted the six drops of venom with 88 drops of glycerine, and various amounts of this mixture were further diluted with distilled water and then injected subcutaneously into pigeons. On November 4, 1886 they began to carefully determine the minimal fatal dose of venom, which was to become the all-important standard for all subsequent tests. After injection, the initial symptom was a weakness in a bird's legs, causing it to sit down or "to move with a tottering gait." If the dose was fatal, the paralysis extended from the legs to the wings and led to general convulsions just before death. Death would occur as soon as three or as late as 20 hours after injection.

FIG. 4. Plaque at the University of Michigan Medical School commemorating Sewall's discoveries on snake venom antitoxins.

The general scheme of the experiments was to inject a glycerine-venom mixture that was dilute enough so that the bird survived, but then to gradually increase the concentration of the mixture injected into the same bird at intervals until it was able to withstand higher and higher concentrations because the bird had developed immunity to the venom. By December 3rd, when the fatal dose of glycerine-venom was 2/3rds of a drop in control birds, they injected as much as 4-1/2 drops, or *about seven times the fatal dose*, into previously inoculated birds without observing any deleterious effects. Later, Sewall and Novy discovered that the resistance to the venom subsided if the birds were not freshly inoculated. One bird, for example, which had shown no effects when 4-1/2 drops were injected on December 3rd, was "… perceptibly weakened by the inoculation on Jan. 6 [1887] of 3 drops of glycerine-venom." The persistence of resistance was shown in another inoculated bird that was injected with "more than 1" drop (i.e., ordinarily a fatal dose) on May 6th. It showed some "weakness" after 24 hours, but ten days later showed no lingering effects at all. All experiments ended on May 19, 1887.

Publication of Results and Responses to Sewall's Paper

Sewall's paper was published in Cambridge, England, in volume 8 (for 1887) of *The Journal of Physiology*, then the leading international journal of its kind. Despite our understanding today of the significance of Sewall's work, there were very few citations to his paper in the literature. However, Albert Calmette, a disciple of Pasteur and the first person to develop snake antiserums,

acknowledged in his book on the venoms of venomous animals and their antivenom serum therapies the primacy of Sewall's discovery (Calmette 1907, p. 253; English edition, 1908, p. 241). (For modern reviews of Calmette's classic work on the development of antitoxic horse serums for use in persons bitten by cobras, see Hawgood 1999, and Adler 2007.) Calmette had followed the techniques he had used in the preparation of diphtheria antitoxins a few years earlier, principles that were in fact pioneered by Sewall.

Calmette's indebtedness to Sewall was formally recognized when he led a delegation of French scientists to the University of Michigan in the early Fall of 1908 to see where Sewall had conducted his experiments with rattlesnakes. Despite the scorching heat that day, the visitors wore formal attire—cutaway coats and silk hats—and carried canes. Novy, Sewall's former assistant, led them to what was by then called the "Old" Medical Building and was able to show them the location of their former laboratory. Sewall, however, was not present because in 1888 he had moved to Colorado where the climate helped to alleviate his tuberculosis. He soon accepted a post at the University of Denver and, by examination, earned his M.D. degree there the next year. He practiced medicine locally and during 1911–1918 was a faculty member at the University of Colorado Medical School. Sewall did, however, return Calmette's favor by visiting him in his lab at the Pasteur Institute in France in 1909. The Old Medical Building suffered an extensive fire in 1911 and was razed in 1914; the site today is occupied by a physics building.

Recognition of Sewall's Classic Studies

Immunizations against disease-causing bacteria and viruses had been known since antiquity. Inoculation for smallpox virus was practiced in India since about 1000 BCE and was well known in China by the late 10th century. In 1796 the British physician, Edward Jenner, was the first to produce a safe method of inoculation for smallpox, by using that virus's close but harmless genetic relative, cowpox. Diphtheria, on the other hand, is caused by an exotoxin, a single polypeptide chain produced by a viral gene inside a bacterial host. In 1890, two German biologists, Emil Adolf von Behring and Paul Ehrlich, announced a method for developing an antiserum against diphtheria; their joint work resulted in Nobel Prizes in 1901 and 1908, respectively. It was Sewall, however, who in 1887 had first demonstrated the principle that immunity can be developed to a chemical molecule, a toxin, by using the complex molecules in snake venom as the stimulus for the immune reaction.

Sewall received many awards for his research including honorary M.D. and Sc.D. degrees in 1888 and 1912, respectively, both from Michigan and a Sc.D. from his *alma mater*, Wesleyan, in 1926. In 1933, a plaque commemorating Sewall's discoveries on rattlesnake antitoxins was erected on a wall in the medical school at Michigan and was dedicated the next year. Today, this plaque is located on the seventh floor of the Medical Sciences II building (Fig. 4). In 1930, Sewall was awarded the Trudeau Medal of the National Tuberculosis Association and the following year, the George Kober Medal of the Association of American Physicians. Thus, Sewall's classic studies, including the first production of antitoxins to snake venoms, were eventually recognized and during his lifetime. He died in Denver of a heart attack in 1936, at the age of 81.

Acknowledgments.—We thank Gregory Schneider of the University of Michigan Museum of Zoology for locating the swamp known as Steere's Swamp. The Bentley Historical Library at the University of Michigan gave assistance with archival material and the scanning of images. We deeply appreciate Barbara Hawgood's critical review of our manuscript.

The Herpetological Contributions of William Beebe: Naturalist, Explorer, and Father of Neotropical Ecology

Few metropolitan regions of the world have produced as rich a legacy of zoo herpetologists as New York City. Together with academic institutions such as the American Museum of Natural History and the city's numerous colleges and universities, zoological parks in New York have played a key role in shaping North American herpetology. Many celebrated herpetologists of the 20th century began their careers with, or became employed mid-career by at least one of New York's six zoological parks, although none of these institutions have supported as a great a lineage of productive herpetologists as the Bronx Zoo (Adler 1989; Brazaitis and Abene 2008; Card and Murphy 2000; Murphy 2007).

For more than a century, reptile curators at the Bronx Zoo (formerly the New York Zoological Park) have made significant

e-mail: odatriad@yahoo.com

contributions to the study of reptiles and amphibians through a variety of research activities and publications (see Murphy 2007). Unfortunately, their works have often overshadowed significant contributions made concurrently by staff members of the zoo's parent organization, the New York Zoological Society (now the Wildlife Conservation Society). For example, Charles Haskins Townsend published several important articles on reptiles, particularly Galapagos tortoises, during his tenure as the director of the New York Aquarium between 1902 and 1937, and had several species of reptiles named in his honor (see Grant 1947). William Beebe, the New York Zoological Park's original bird curator and founding director of the society's Department of Tropical Research, was also responsible for many important contributions to herpetology. As colleagues of Raymond Ditmars, the zoological park's original, and perhaps most celebrated reptile curator, Townsend's and Beebe's important work with reptiles and amphibians is often overlooked in part due to Ditmars' many publications and widespread popularity as the chief herpetologist of the society during its early history (e.g., Adler 1989; Murphy 2007; Wood 1962).

Although not a strict herpetologist given his background in ornithology and broad interests in ecology and natural history, William Beebe's important contributions to the study of reptiles and amphibians rivaled those of many professional herpetologists of the period. Yet surprisingly, despite authoring numerous articles and book chapters on the ecology and behavior of reptiles and amphibians and collecting thousands of herpetological voucher specimens, Beebe has seldom been recognized in works on herpetological history (e.g., Murphy 2007, 2008). This is not to say, however, that his name is unfamiliar among herpetologists, as Beebe is perhaps best known as one of America's greatest naturalists and explorers, and for his pioneering work in the fields of ecology, marine biology, and wildlife conservation (Gould 2004; Welker 1975). Here, I highlight the impressive career and herpetological contributions of William Beebe, the father of neotropical ecology. Readers interested in more detailed accounts of his life, travels, and career should refer to the important works of several biographers and historians (Berra 1977; Bridges 1974; Gould 2004; Welker 1975).

Life and Career

Charles William Beebe was born in Brooklyn, New York in 1877. Growing up in rural New Jersey, he developed a strong interest in natural history, and amassed an impressive personal collection of zoological specimens, especially birds (Welker 1975). At Columbia University, he studied within the Department of Zoology from 1896 to 1898, but left before graduating for a position with the newly formed New York Zoological Society (NYZS) (Welker 1975). Although he would eventually receive honorary doctorates from both Colgate University (LL.D) and Tufts College (Sc.D) in 1928 (Berra 1977; Crandall 1964) and was identified as "Dr." in many of his later written works and by peers, Beebe never officially completed a baccalaureate degree. Nevertheless, the lack of a traditional academic background would not hinder his career or literary success, or the scope and magnitude of his scientific achievements.

Beebe was hired by the NYZS in 1899 as the assistant curator of ornithology at its newly established zoological park in the Bronx. During his first few years with the society, he assembled a sizeable collection of live birds and oversaw the design and construction of several new buildings and aviaries, and in 1902 was promoted to curator of birds (Bridges 1974). In 1903, Beebe departed on the first of more than 50 scientific expeditions that he would lead during his career with the NYZS, a self-funded trip to Mexico with his wife to study, identify, and collect birds for the zoological park (Beebe 1905a). This trip was followed by collecting trips to Trinidad, Venezuela, and British Guiana (now Guyana) in the following years (Beebe and Beebe 1910), and in late 1909, he embarked on an extensive year-and-a-half-long expedition to the Far East to study pheasants, which eventually culminated in his monumental and perhaps most celebrated publication, "*A Monograph of the Pheasants*" (Beebe 1918–1922).

Beyond his curatorial duties at the zoological park and his increasing research and collecting activities in the field, Beebe was also interested in paleontology, particularly the ancestry of birds and the evolution of flight (e.g., Beebe 1938a, 1942a). In 1915, he authored a theoretical paper that predicted the existence of an intermediate four-winged, or "Tetrapteryx" stage in the evolution of flighted dinosaurs (Beebe 1915) that preceded *Archaeopteryx*. His ideas were largely dismissed or forgotten for 85 years until the discovery of *Microraptor* (Xu et al. 2000), a small, four-winged therapod whose features nearly mirror those of his original "Tetrapteryx" illustration (Beebe 1915). Since 2000, several species of *Microraptor* have been discovered (e.g., Gong et al. 2012; Xu et al. 2003), and his original idea of avian flight evolving from a four-winged ancestor continues to gain support as additional fossil material is located (e.g., Zheng et al. 2013).

In 1915, he traveled to Brazil to arrange a shipment of birds for the zoological park in New York, and it was during this trip that his research interests began to change (Welker 1975). Stopping to investigate and inventory the organisms found around a large jungle tree (Beebe 1916a,b,c), this study marked a departure from his widespread ornithological collecting to more refined and intimate investigations on the ecology of tropical forest ecosystems (e.g., Beebe 1925b).

> "*Again and again we have proved the value of limited, concentrated investigations over wider-ranging, thinner exploration.*"
>
> —William Beebe, High Jungle, 1949:187

With assistance and support from former US President Theodore Roosevelt, a close friend and founding chairman of the NYZS, Beebe established Kalacoon, an ecological research station located in northeastern Guyana in 1916 (Beebe 1919; Beebe et al. 1917; Gould 2004). Impressed by his research and collecting activities abroad, the NYZS founded the Department of Tropical Research in 1916 and appointed Beebe as its directing curator (Welker 1975). This appointment officially relieved him of all curatorial duties at the zoological park and enabled him to focus chiefly on his fieldwork and writings (Bridges 1974). Over the next four decades, he led numerous expeditions with the department to poorly surveyed terrestrial and marine environments of the neotropics and established field stations at various locations in South America (Beebe 1925b, 1949a,b, 1952; Beebe and Crane 1947). Staffed by naturalists, hunters, artists, and taxidermists, the Department of Tropical Research under Beebe's direction procured tens of thousands of zoological voucher specimens, photographs, artwork, and film footage depicting wildlife encountered through its expeditions. Hundreds of scholarly articles, notes, and reports were produced by the department, and covered a broad range of topics including, but not limited to, taxonomy, ecology, ethology, and marine biology.

FIG. 1. William Beebe in collecting mode, Guyana, 1917.

Returning to Guyana in 1919, the department established Kartabo, a field research station located just upriver from the former site of Kalacoon (Welker 1975). There, over several seasons, Beebe and his staff intensively studied the ecology of a small tract of jungle roughly 65 ha in size (e.g., Beebe 1925b).

Aside from his interests in tropical forest ecology, Beebe had long been fascinated by marine environments and even experimented with underwater diving equipment (e.g., Beebe 1926, 1934) more than a decade before famed oceanographer Jacques Cousteau. During the late 1920s and throughout the 1930s, Beebe focused the Department of Tropical Research's expeditions heavily on oceanographic exploration. These included expeditions to survey and study the marine life of the Galapagos Islands (Beebe 1926), Haiti (Beebe 1928), Bermuda (Beebe 1932), and the Gulf of California (Beebe 1938b), as well as Beebe's unprecedented and record-setting half-mile (ca. 805 m) descent inside a steel bathysphere in 1934 (Beebe 1934). At this depth in waters off of Bermuda, he became the first biologist to observe deep sea life in situ, including bioluminescent organisms and many species unknown to science (Beebe 1934).

In 1941, Beebe and his department returned to studying terrestrial ecosystems, carrying out ecological investigations in Caripito, Venezuela (Gould 2004), and then later establishing Rancho Grande, a field station headquartered inside the former jungle palace of Venezuelan dictator Juan Vicente Gómez, in 1945. There, the department studied the ecology of the surrounding cloud forest over a period of three years (Beebe 1949a). In 1949, Beebe purchased Simla, an estate located in the Arima Valley of Trinidad's Northern Range, which he established as a tropical research station and later gifted to the NYZS (Gould 2004).

Beebe officially retired in 1952 as Director Emeritus of the Department of Tropical Research after more than 50 years of service with the NYZS, but remained active in field research up until his death in Trinidad in 1962 (Bridges 1974; Gould 2004; Welker 1975).

Publications History

"No American naturalist of recent times has given us so copious and detailed a record of his work, his travels, the challenges he faced and his response to them. These books were not merely of scientific reportage, but of scientific adventure; more important, they were creative works, informed by an intelligence of extraordinary range and a style and consciousness highly literary."

—Robert H. Welker, Natural Man: The Life of William Beebe, 1975:xii

Beebe was a gifted and prolific writer, authoring 24 books and more than 800 articles, reviews, and reports over the span of his career (Berra 1977). Many of his technical works, which numbered in the hundreds (Crandall 1964), were published in *Zoologica*, the official research journal of the NYZS which was initially founded in 1907 as a publishing outlet for Beebe's research (Bridges 1974), and included taxonomic treatises (including the descriptions of some 87 species of fishes and one bird) as well as studies on the ecology and behavior of birds, mammals, amphibians, reptiles, fishes, and arthropods (Berra 1977). Many additional biological accounts and notes on the husbandry of birds at the zoological park were published in the *Bulletin of the New York Zoological Society*, which became *Animal Kingdom* in 1942.

Most of Beebe's books and popular articles shared extensive details of his travels and experiences abroad, gaining him widespread popularity and celebrity status, to the extent where his personal affairs became fodder for headlines in major US newspapers (Gould 2004; Welker 1975). He regularly contributed to several high profile magazines including *Atlantic Monthly*, *Harpers*, and *Ladies Home Journal*, among others, where he popularized science, natural history, and exploration. Many of these works were later republished as chapters in his books.

Herpetological Contributions

The vast majority of William Beebe's herpetological contributions stem from his field investigations and collecting activities in Guyana, Venezuela, Trinidad, and the Galapagos Islands, although some additional accounts briefly described the natural history, occurrence, or behavior of herpetofauna encountered during trips to Asia (Beebe 1927), the Caribbean (Beebe 1918), Mexico (Beebe 1905a,b 1938b), and Central America (Beebe 1942b).

Collections.—As depicted by the iconic 1917 photograph taken of him in Guyana with butterfly net and rifle in hand (Fig. 1), Beebe was a prolific collector of zoological specimens, and made no exceptions for reptiles and amphibians. Inventories of herpetofauna collected by Beebe and his staff during expeditions to South America are vast, and appear in several publications (e.g., Beebe 1919a, 1925b, 1944a,b, 1945, 1946a, 1952). Because his knowledge of reptile and amphibian taxonomy was limited, he frequently sought assistance from G. K. Noble and Charles Bogert at the American Museum of Natural History (AMNH), and

Karl Schmidt at the Field Museum of Natural History, in identifying specimens collected in South America (e.g., Beebe 1944a,b, 1945, 1946a; Myers 2000). Despite tensions arising between Beebe and AMNH staff over the identification of some of his herpetological specimens, most of his collections were eventually gifted to the museum's herpetology department (Myers 2000). In fact, Myers (2000) noted that Beebe's 50-plus years of collections with the NYZS represent the best example of material deposited in the museum's herpetology section by non-AMNH led expeditions. Major collections from Beebe deposited in the AMNH include those from Guyana (>1100 specimens), Venezuela (700 specimens), and Trinidad (>150 specimens) (Myers 2000). Additional voucher material was deposited in several other American museums and institutions abroad including the Georgetown Museum in Guyana (e.g., Beebe 1945). At least ten holotypes were collected by Beebe (Table 1).

In recognition of his contributions, at least five species of herpetofauna have been named after Beebe, although most now represent junior synonyms (Table 2). *Plasmodium beebei*, a protozoal lizard parasite of the gekkonid genus *Gonatodes,* was also named in his honor (Telford 1978).

Besides voucher material, Beebe also collected many specimens that were delivered alive to the New York Zoological Park for display in its reptile house. Noteworthy specimens included *Amblyrhynchus cristatus*, *Conolophus subcristatus*, and *Tropidurus* spp. (now *Microlophus*) from the Galapagos Islands (Beebe 1923a, 1924), and *Platemys platycephala*, *Chelus fimbriatus*, *Testudo tabulata* (now *Chelonoidis denticulata*), *Caiman sclerops* (now *C. crocodilus*), *Polychrus marmoratus, Boa constrictor* (including a 3.8-m long individual), *Bothrops atrox*, *Chironius carinatus, Corallus cooki, Crotalus durissus, Eunectes murinus*, *Helicops angulata* (now *H. angulatus*), *Lachesis muta, Pseustes sulphureus*, *Siphlophis cervinus*, *Spilotes pullatus*, and *Gastrotheca ovifera* from Guyana and Venezuela (Beebe 1918a, 1923c, 1925b, 1946a, 1949a; Beebe and Beebe 1910). From Southeast Asia, he collected and sent back live specimens of gliding reptiles including *Draco volans*, *Ptychozoon* sp., and *Chrysopelea ornata* (Gould 2004).

Field investigations:

Anurans

> *"The humble polliwog in its development is significant of far more marvelous facts than the caterpillar changing into the butterfly, embodying as it does the deepest poetry and romance of evolution."*
>
> —William Beebe, The Log of the Sun, 1906:112

Beebe showed a particular fondness for frogs, especially their development, courtship behaviors, and calls, and devoted several articles and book chapters to these subjects (Beebe 1906, 1921a,b, 1946b, 1947a, 1953). In Guyana, he described the nesting habits and larval emergence of *Phyllomedusa bicolor* from leaves overhanging water (Beebe 1921a), provided information on the ecology of *Leptodactylus caliginosus* (now *L. latrans*) including its behavior and defensive call, described the call of *Hyla maxima* (now *Hypsiboas boans*) (Beebe 1922, 1925a), and provided details on the predator-prey relationships and stomach contents of 36 frog species from the region (Beebe 1925b). In Venezuela, he documented the call, courtship behaviors, and

Table 1. Holotypes collected by William Beebe in the collection of the American Museum of Natural History (AMNH). Current taxonomic conventions for amphibians and reptiles are based on Frost (2013) and Uetz (2013), respectively.

Table 2. Reptile and amphibian taxa named after William Beebe. Current taxonomic conventions for amphibians and reptiles are based on Frost (2013) and Uetz (2013), respectively.

Order	Family	Taxon named after Beebe	Current taxonomy
Anura	Eleutherodactylidae	*Eleutherodactylus beebei* Chochran, 1956	*Eleutherodactylus inoptatus* (Barbour, 1914)
	Bufonidae	*Bufo beebei* Gallardo, 1965	*Rhinella humboldti* (Gallardo, 1965)
	Aromobatidae	*Hyloxalus beebei* Noble, 1923	*Anomaloglossus beebei* (Noble, 1923)
Squamata	Gekkonidae	*Gehyra beebei* De Rooij, 1915	*Gehyra mutilata* (Wiegmann, 1834)
	Sphaerodactylidae	*Gonatodes beebei* Noble, 1923	*Gonatodes annularis* Boulenger, 1887

tadpole carrying behavior of *Prostherapis trinitatis* (now *Mannophryne trinitatis*), as well as the anatomy, defensive behavior, and reproductive biology of *Gastrotheca ovifera* (Beebe 1949a).

In Guyana, Beebe was the first to discover a population of a smaller-sized *Pipa*, which was later identified as a new species, *P. aspera* Müller 1924 (Beebe 1925b).

Saurians

> *"Bound to the ground by their short scales and four limbs, these small lizards are yet remarkably birdlike in their vivacity and their enthusiastic playing of their little game of life."*
>
> —William Beebe, Jungle Peace, 1918:43

Lizards are prominently featured in Beebe's writings on herpetology and appear to have been his most extensively studied group. In his book, *Jungle Peace*, he recalled first being taught how to noose lizards by a 12-year-old girl on the island of St. Thomas, thereby enabling him to more closely study members of this group (Beebe 1918a). In the Gulf of California, he documented the color variation and behaviors of insular lizard populations (Beebe 1938b), and recorded observations on the coloration, activity, and defensive behaviors of *Ctenosaura acanthura* in Mexico (Beebe 1905a, b). In 1919, he described in detail the geographic variation and ontogenetic color changes in lizards of the genus *Ameiva*, and discussed their relevance to Barbour and Noble's (1915) recent taxonomic revision of the genus (Beebe 1919b).

During a brief visit to the Galapagos Islands in 1923, Beebe studied many aspects of the ecology and behavior of the archipelago's lizard fauna (Beebe 1924). He described the differences in coloration between island populations of *Tropidurus* (now *Microlophus*), and discussed the possibility that insular populations of these animals within the archipelago could have originated through rafting on debris (Beebe 1923a). Captivated by the languid behavior and tameness of *Amblyrhynchus cristatus*, he carried out several crude behavioral experiments to study their lack of fear towards humans:

> *"To test the acquisition of fear, I caught an iguana of medium size, jerked him into the air, played with him for a few minutes and then loosened the noose and set him free. He ran off a few feet, turned and looked at me and offered no resistance to being again caught and swung through space. Six times I repeated this, and if anything he was tamer after the rough treatment than before, in the face of a series of experiences which would have driven any ordinary wild creature insane with fright."*
>
> —William Beebe, Galapagos: World's End, 1924:119

In addition to recording information on the diet, activity, and behavior of *A. cristatus*, Beebe also documented parasitism in the species, including the mutualistic removal of ticks by the Scarlet Rock Crab, *Grapsus grapsus* (Beebe 1924). He studied various aspects of the ecology of *Conolophus subcristatus* on Baltra Island, and observed mockingbirds removing ticks from its skin, which were later determined to be a new species (Beebe 1924).

Beebe's most important scientific works on lizards were a series of technical articles that provided extensive ecological data for 41 species collected in Guyana and Venezuela (Beebe 1944a,b, 1945). Particularly noteworthy from these reports were detailed descriptions, measurements, and line drawings of eye and hyoid morphologies for many of the species discussed, as well as a discussion on the termitaria-nesting habits of *Tupinambis*. In an earlier report, he provided detailed information on the ecology of 31 species in Guyana, including a comparison of the stomach contents of *Ameiva* and *Cnemidophorus* (Beebe 1925b).

Serpentes

> *"But their movements are slow, and rather than pursue their prey, their forte in life is waiting, with all the patience in the world, for some small creature to cross the spot which they have rendered more deadly than any pitfall or trap of human devising."*
>
> —William Beebe, Noosing a bushmaster, 1916:1375

Intrigued by bushmasters, Beebe described close encounters with *Lachesis muta* as well as their capture, and provided general information on the natural history and habits of the species (Beebe 1916c, 1918a). Of particular interest, he noted that *L. muta* emitted a delicate, but noticeable odor when alarmed or disturbed (Beebe 1925b), and even asserted his ability to detect the presence of the species by smell while blindfolded (Beebe 1949a)!

In 1925, he provided detailed information on the ecology of 52 snake species collected from a small section of forest in Guyana (Beebe 1925b). A follow-up study that included data from both Guyana and Venezuela yielded extensive data on the ecology of 54 species (Beebe 1946a). Among this information, Beebe (1946a) described a peculiar liana-mimicking behavior and defensive behavior in *Pseustes poecilonotus*. In the Galapagos Islands, he studied the stomach contents, reproductive biology, and geographical variation of *Dromicus* spp. (now *Pseudalsophis*) (Beebe 1924), and in Costa Rica, he recorded notes on the behavior and natural history of *Pelamis platurus* (Beebe 1942b).

As a collector of many snake specimens, Beebe (1947b) became frustrated by the loss of scale coloration through fixation and preservation, particularly with coral snakes of the genus

Micrurus. This prompted him to develop a novel method of preserving and mounting snake skins so that their colors remained vivid as in life (Beebe 1947b).

In 1952, Beebe produced an inventory of snakes native to the Arima Valley of Trinidad, reporting a total of 27 species (Beebe 1952). Many decades later, Boos (2001) noted some mistakes in Beebe's (1952) list, such as his inclusion of *Oxybelis fulgidus* as an inhabitant of Trinidad. As that species has never been collected in Trinidad, Boos (2001) suspected that this error represented a mistaken locality for nearby Patos Island.

Testudines

> *"I have seen these turtles in both hemispheres and along the shores of four continents, but not until my week on Clarion Island did green turtles leave the realm of exclamatory recognition and become exciting individuals, objects of intense interest and wonder."*
>
> —William Beebe, Zaca Venture, 1938: 276

Over the course of his many oceanic voyages with the Department of Tropical Research, Beebe had the opportunity to observe many sea turtles, particularly *Chelonia mydas*. During an excursion to Clarion Island, off the west coast of Baja California, he made extensive observations on *C. mydas*, and described in detail the stomach contents and nesting biology of the species, reviewed earlier accounts of its biology, and clarified anthropomorphic misconceptions regarding its reproduction (Beebe 1938b).

In his book, *Galapagos: World's End*, Beebe (1924) offered an extensive review of historical accounts dating back to 1684 that described encounters with Galapagos tortoises and their exploitation, as well as scientific expeditions that had collected individuals from the archipelago. On Pinzón Island, his crew located and secured a single tortoise, whose behavior and climbing abilities up steep, rocky slopes were studied by Beebe (1924).

Interestingly, Beebe rejected the idea that the terrestrial fauna of the Galapagos Islands had originated by overwater emigration from mainland South America; insisting instead that there must have once been a land bridge connection (Beebe 1924). This position appears to have been reinforced by a crude experiment carried out aboard his ship, whereby the tortoise collected from Pinzón was tossed into open water to see if it could float. Much to Beebe's surprise, the tortoise not only floated upright, but was also capable of controlled swimming as it attempted to climb back aboard a rowboat. Its death aboard the ship one week later, which Beebe attributed to congestion in the lungs caused by the inhalation of sea water while swimming, led him to the conclusion that:

> *"This would negative any possibility of the tortoises being able to make their way over wide expanses of water, either from the mainland or from island to island, in spite of their unusual swimming ability."*
>
> —William Beebe, Galapagos: World's End, 1924:228

In Guyana, Beebe et al. (1917) described the nesting habits and ecology of several species of freshwater turtles, but provided only local names for the species, complicating their identification. Beebe (1925b) collected basic ecological data on eight turtle species in Guyana, and on Trinidad, he recorded the occurrence of two species from the Arima Valley (Beebe 1952).

Crocodilians

> *"Common in many places and actually abundant in a few, these great saurians are far less conspicuous than their infinitely smaller relatives- the lizards which everywhere scamper up tree-trunks or barge clumsily through the fallen leaves."*
>
> —William Beebe et al., The Alligators of Guiana, 1917:283

Although he had observed them in both eastern and western hemispheres, and even collected specimens for museums, Beebe's writings on crocodilians appear to be limited to encounters with caimans in Guyana. There, he and others reported on the ecology and anthropogenic threats to caiman (probably *C. crocodilus*) living in the vicinity of Georgetown (Beebe 1917; Beebe et al. 1917), and briefly described the stomach contents of a young *C. sclerops* (now *C. crocodilus*) (Beebe 1925b). Beebe et al. (1917) reviewed local accounts of attacks on Guyanese villagers by *C. niger* (now *Melanosuchus niger*).

Captivity-based investigations

To supplement their field investigations, Beebe and his staff regularly maintained live reptiles and amphibians in their field station laboratories. In addition to providing opportunities for observing cryptic behaviors and developmental processes, maintaining specimens in the laboratory also served as a way of keeping them alive and healthy in preparation for their delivery to the zoological park in New York.

Frogs were frequently kept subjects, and led to the discovery of many fascinating behaviors and developmental processes that had not been seen or documented before. For example, Beebe (1946b; 1947a, 1949a) was the first to describe the "birth" or emergence of newly metamorphosed froglets from the dorsal pocket of the marsupial frog, *Gastrotheca ovifera*, and described larval development and metamorphosis in *Phyllomedusa bicolor* (Beebe 1921a,b). Several additional frog species were maintained in the laboratory, including *Leptodactylus caliginosus* (now *L. latrans*), *Phyllobates inguinalis* (now *Colostethus inguinalis*) (Beebe 1921a), *Prostherapis trinitatis* (now *Mannophryne trinitatis*), *Bufo marinus* (now *Rhinella marina*), *Atelopus cruciger,* and *Hyla rubra* (now *Scinax ruber*) (Beebe 1925b; 1949a).

Snakes were also regularly kept in terraria. On one occasion, Beebe (1949a) recalled tripping over an escaped coral snake (*Micrurus* sp.) while walking through a dark laboratory at night. A large *Bothrops asper* that was thought to have recently consumed a large meal was captured in the hallways of Rancho Grande and temporarily housed in a terrarium (Beebe 1949a). Several days after its capture, it unexpectedly gave birth to 28 live offspring, yielding important details about the reproductive biology of the species, and possibly representing the first birth of the species in captivity. Additional snake species kept included *Boa constrictor*, *B. canina* (now *Corallus caninus*), *Chironius carinatus*, *Pseustes sulphureus*, and *Tantilla melanocephala* (Beebe 1946a).

Many lizards including *Anolis nitens* (now *A. chrysolepis*), *A. sagrei*, *Cnemidophorus lemniscatus*, *Gonatodes annularis*, *Mabuya mabouya*, *Plica umbra*, *Polychrus marmoratus*, and *Uranoscondon superciliosa* (now *U. superciliosus*) were kept and studied in the laboratory, with eggs from several species laid in

captivity (Beebe 1944a,b, 1945). Although most eggs were dissected to study their development, some were artificially incubated and left to hatch in the lab. For example, Beebe (1945) described the successful captive hatching of *Tupinambis nigropunctatus* (now *T. teguixin*) and documented, perhaps for the first time, that disturbances to the surface of the eggshells prompted the pipping and rapid emergence of hatchlings (1925a). Today, this technique is often used by herpetoculturists to trigger hatching in tegu eggs. *Gonatodes annularis* was also successfully hatched in the laboratory (Beebe 1944a), and neonatal *M. mabouya* (now *Varzea bistriata*) were born to captive females (Beebe 1945).

On the voyage back to New York from the Galapagos Islands, a large group of *C. subscristatus* destined for the zoological park was maintained aboard the ship and fed a diet of lettuce and cabbage (Beebe 1923a). A group of *A. cristatus* was also brought back to New York on the same trip, but not on board the ship. Instead, they were housed for the duration of the two-month journey inside a floating wire cage that was pulled by the ship (Beebe 1923a, 1924). Although the animals survived the trip, they could not be encouraged to feed on any of the seaweed or vegetable matter offered to them (Beebe 1923a).

Miscellany.—Several of Beebe's published works on herpetology were accompanied by skillful illustrations painted by Department of Tropical Research artist Isabel Cooper. These included both color and black-and-white illustrations of *Conolophus subcristatus, Tropidurus albemarlensis* (now *Microlophus albemarlensis*), and *Amblyrhynchus cristatus* in Beebe's (1924) book, *Galapagos: World's End*, as well as nearly 100 black-and-white illustrations accompanying his technical articles on the ecology of lizards and snakes from Guyana and Venezuela (Beebe 1944a,b, 1945, 1946a).

Beebe authored the foreword to Curran and Kauffeld's (1937) popular book, *Snakes and their Ways,* and prepared the introduction to Tweedie's (1956) article on flying lizards of the genus *Draco*. Popular accounts on the etymology of reptile and amphibian common names were also given (Beebe,1905a, 1906).

Closing Remarks

In retrospect, William Beebe's impact on the field of herpetology extends far beyond the observable contributions hitherto discussed. Together with his important fieldwork in other disciplines, including ornithology, ichthyology, and entomology, Beebe's herpetological investigations have helped stress the importance of studying not only the animals, but their ecological roles and relationships with other organisms. His pioneering fieldwork in the neotropics was critical in paving the way for future researchers and studies in the emerging fields of ecology and conservation biology.

Beebe's impressive career demonstrated that an academic background was not necessarily a prerequisite for carrying out important scientific investigations or becoming a leading contributor to a particular field. Indeed, the breadth and extent of his lifetime scientific achievements surpassed those of most of his academic contemporaries.

It is impossible to discuss the impacts of Beebe's contributions on the fields of ecology, conservation biology, or herpetology without noting his critical role in the history and development of the New York Zoological Society. It was largely Beebe's pioneering fieldwork and oversight of the Department of Tropical Research that prompted the society's outward growth from an organization established upon zoological park management to a driving force in wildlife research and conservation. Concerned about the welfare of his zoological park, if founding NYZS director William Hornaday had gotten his way, Beebe would not have been permitted to take such extensive stints away from his curatorial duties at the zoo (Bridges 1974); this would have limited or even prohibited his collecting and research activities in the field. Fortunately, seeing the importance of his fieldwork, influential members of the society's executive committee disagreed with Hornaday's position and fully encouraged and supported Beebe's research endeavors (Bridges 1974). Without Beebe's dedication and investment of his personal finances towards fieldwork abroad (Gould 2004), it is unlikely that the Department of Tropical Research would have been founded and sustained. Without the important work carried out by the department under his direction, it is doubtful that the society would have followed the same trajectory towards becoming the Wildlife Conservation Society (WCS), the world's largest wildlife conservation organization. Today, the WCS supports and manages hundreds of field-based conservation initiatives throughout the world, including many which focus on conserving reptile and amphibian populations and their habitats.

Finally, of the many formal and informal roles that Beebe assumed during his lifetime, perhaps the most important was his popularization of science, nature, and exploration. His writings invited readers of a broad audience to relive his remarkable experiences as a naturalist traveling the world in search of wildlife and wild places, and have been attributed to inspiring and launching the careers of many renowned naturalists, ecologists, and conservation biologists, including Ernst Mayr, E. O. Wilson, Roger Tory Peterson, Rachel Carson, and Sylvia Earle (Gould 2004; Welker 1975; Wilson 1994), as well as many professional and amateur herpetologists (e.g., Bartlett 1988). Beebe's far-reaching influence continues to this day, as reprints and older copies of his books continue to be purchased and read by the next generation of naturalists and conservationists.

Acknowledgments.—I thank Aja Marcato, Louis Porras, Robert Hansen, and the library staff of the American Museum of Natural History (AMNH) for their assistance with sourcing literature; Jennifer Pramuk helped clarify current binomials for several amphibian taxa; David Dickey and the Department of Herpetology of the AMNH kindly permitted the use of data from the AMNH's collections database. Lastly, I thank Raphael Pelegrino and the Wildlife Conservation Society for the use of their photograph, Sam Sweet for feedback on an earlier draft of this manuscript, and Jim Murphy for his encouragement and support of this manuscript.

GEOGRAPHIC DISTRIBUTION

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of a species' range, and thereby permit a more significant interpretation of its biology.

These geographic distribution records will be accepted in a **standard format** only, and all authors *must* adhere to that format, as follows: SCIENTIFIC NAME, STANDARD ENGLISH NAME if available (for the United States and Canada as it appears in Crother [ed.] 2012. *Scientific and Standard English Names of Amphibians and Reptiles of North America North of Mexico, with Comments Regarding Confidence in Our Understanding.* 7th ed. Herpetol. Circ. 39:1–92 [available from ssarbooks.com], for Mexico as it appears in Liner and Casas-Andreu 2008. *Standard Spanish, English and Scientific Names of the Amphibians and Reptiles of Mexico.* Herpetol. Circ. 38:1–162), LOCALITY (use metric for distances and give precise locality data, including lat/long coordinates in **decimal degrees** and cite the map datum used), DATE (day-month-year), COLLECTOR, VERIFIED BY (*cannot* be verified by an author; curator at an institutional collection is preferred), PLACE OF DEPOSITION (where applicable, use standardized collection designations as they appear in Sabaj Pérez [ed.]. 2013, *Standard Symbolic Codes for Institutional Resource Collections in Herpetology and Ichthyology: an Online Reference*, ver. 4.0, available at http://www.asih.org/) and CATALOG NUMBER (required), COMMENTS (brief), CITATIONS (brief and must adhere to format used in this section; these should provide a geographic context for the new record). Close with author name(s) in bold, capital letters (give name and address in full—spell out state or province names—no abbreviations, e-mail address after each author name/address for those wishing to provide it—e-mail required for corresponding author). Please include distance from nearest previously known record (provide a citation or refer to existing vouchered material to substantiate your report). If publishing specific locality information for a rare or endangered species has the potential to jeopardize that population, please consult with the Section Editor at time of record submission. If field work and/or specimen collection occurred where permits were required, please include permit number(s) and authorizing agency in the text of the note.

Some further comments. The role of the "Standard Names" lists (noted above) is to standardize English names and comment on the current scientific names. Scientific names are hypotheses (or at least represent them) and as such their usage should not be dictated by a list, society, or journal.

Additionally, this geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens that have been placed in a university or museum collection (private collection depository records are discouraged; institutional collection records will receive precedence in case of conflict). A good quality photograph (print, slide, or digital file) may substitute for a preserved specimen. Photographic vouchers *must* be deposited in a university or museum collection along with complete locality data, and the photographic catalog number(s) must be included in the same manner as a preserved record. Before you submit a manuscript to us, check Censky (1988, *Index to Geographic Distribution Records in Herpetological Review: 1967–1986*; available from the SSAR Publications Secretary), subsequent issues of *Herpetological Review*, and other sources to make sure you are not duplicating a previously published record. The responsibility for checking literature for previously documented range extensions lies with authors. **Do not submit range extensions unless a thorough literature review has been completed.**

For reports concerning **introduced species**, it is important to note whether a population has become established or if the report represents an isolated occurrence, such as a released captive. Additionally, it will be helpful to include any information that establishes a timeline for the introduction, such as date of first observation.

Please submit any geographic distribution records in the **standard format only** to one of the Section Co-editors: **David C. Blackburn** (Africa and Europe), **Indraneil Das** (Asia), **Stephen Richards** (Australasia, South Pacific) **Jerry D. Johnson** (Mexico and Central America, including the Caribbean Basin), **Alan M. Richmond** (USA & Canada), or **Gustavo J. Scrocchi** (South America). Short manuscripts are discouraged, and are only acceptable when data cannot be presented adequately in the standard format. **Electronic submission of manuscripts is required** (as Microsoft Word or Rich Text format [rtf] files, as e-mail attachments)**.** Refer to inside front cover for e-mail addresses of section editors.

Recommended citation for new distribution records appearing in this section is: Cabral, H., and A. Caballero. 2012. Geographic distribution: Paraguay, Departamento Central: *Pseudoeryx plicatilis*. Herpetol. Rev. 43:622.

CAUDATA — SALAMANDERS

***AMBYSTOMA FLAVIPIPERATUM* (Yellow-peppered Salamander).** MÉXICO: JALISCO: Municipality of Tecolotlán: Presa del Ahogado 3 km S of Quila El Grande (20.318722°N, 104.078320°W; WGS84), 1995 m elev. 13 July 2009. Iván T. Ahumada-Carrillo, Óscar F. Reyna-Bustos, and Carlos Vázquez-Ruiz. Verified by Jacobo Reyes Velasco. UTADC 6908. New municipality record, extending the range 60 km (airline) WSW from type locality at Santa Cruz, Jalisco (Dixon 1963. Copeia 1963:99–101). The salamander was found in pine forest.

IVÁN T. AHUMADA-CARRILLO (e-mail: lepidus320@hotmail.com.), **ÓSCAR F. REYNA-BUSTOS**, and **CARLOS VÁZQUEZS-RUIZ**, Centro Universitario de Ciencias Biológicas y Agropecuarias, Universidad de Guadala-

jara, carretera a Nogales Km. 15.5, Las Agujas, Nextipac, Zapopan, Jalisco, México.

***AMBYSTOMA OPACUM* (Marbled Salamander)**. USA: NORTH CAROLINA: Madison Co.: Pisgah National Forest, 5.4 km airline NW town of Hot Springs (35.92162°N, 82.87714°W; WGS 84). 28 October 2013. Charles R. Lawson. Verified by William M. Palmer. North Carolina State Museum of Natural Sciences (NCSM 81251). First vouchered specimen for Madison County (NCSM files and Beane et al. 2010. Amphibians & Reptiles of the Carolinas and Virginia, 2nd ed. University of North Carolina Press, Chapel Hill. 274 pp.). Collection represents the northernmost known occurrence to date in the Mountain region of North Carolina (Beane et al. 2010, *op. cit.*). Closest previous historical records in the state are from French Broad River floodplain and upland, mixed hardwood forest, Buncombe Co., 54.1 km airline SSE (NCSM 52284, 59016) (NCSM files). Young adult male (TL = 75.1 mm, SVL = 45.2 mm) collected during visual encounter surveys of coverboard arrays at French Broad River floodplain pools.

Two other specimens were found nearby but not vouchered. On 18 October 2011 a gravid female was found 0.51 km airline ENE of vouchered specimen, and on 14 March 2013 two gilled larvae were found 0.25 km airline E of vouchered specimen.

LORI A. WILLIAMS, North Carolina Wildlife Resources Commission, 177 Mountain Laurel Lane, Fletcher, North Carolina 28732, USA (e-mail: lori.williams@ncwildlife.org); **CHARLES R. LAWSON**, North Carolina Wildlife Resources Commission, P.O. Box 289, 517 Tarhelia Heights Road, Whittier, North Carolina 28789, USA (e-mail:charles.lawson@ncwildlife.org); **DOROTHY C. BROWN**, 7203 Jameson Pass, Alpharetta, Georgia 30022, USA (e-mail: blackbear524@hotmail.com); **DANIELLE M. BOUCHONNET**, 1062 Matlock Creek Road, Franklin, North Carolina 28734, USA (e-mail:daniellebouchonnet@gmail.com); **GABRIELLA DANCOURT**, 270 Hi Alta Avenue, Asheville, North Carolina 28806, USA (e-mail: dancourtg@gmail.com); **JEFFREY C. BEANE**, North Carolina State Museum of Natural Sciences, 1626 Mail Service Center, Raleigh, North Carolina 27699-1626, USA (e-mail: jeff.beane@naturalsciences.org).

***AMBYSTOMA TALPOIDIUM* (Mole Salamander)**. USA: NORTH CAROLINA: McDowell Co.: Box Creek Wilderness - Thompson Tract (35.538067°N, 81.963128°W; WGS 84; elev. ~320 m). 11 October 2013. Christopher R. Wilson. Verified by James W. Petranka. NCSM photographic voucher CRW 13-1. New county record (Jeffrey C. Beane, NC State Museum of Natural Sciences). Three paedomorphic larvae, measuring 54–57 SVL and 101–114 TL, were captured using aquatic funnel traps set in floodplain pools within a Montane Alluvial Forest (small river subtype). The property is owned by 130 of Chatham LLC, a private land conservation company.

CHRISTOPHER R. WILSON, Unique Places LLC, 9 Bradford Pl, Hendersonville, North Carolina 28791, USA; e-mail: critterfro@gmail.com.

***DESMOGNATHUS FUSCUS* (Northern Dusky Salamander)**. USA: INDIANA: Floyd Co.: Mt. St. Francis Monastery (38.333706°N, 85.910569°W; WGS 84). 15 June 2013. Andrew Hoffman, Todd Pierson. Verified by Kenneth Krysko. Florida Museum of Natural History (UF-Herpetology 171905 photo voucher). New county record (Minton 2001. Amphibians and Reptiles of Indiana. Indiana Academy of Science, Indianapolis, xiv + 404 pp.). Multiple adults were found under cover in a large, muddy seepage beneath the spillway of Mt. St. Francis Lake.

ANDREW HOFFMAN, Indiana State University, Terre Haute, Indiana 47802, USA (e-mail: ahoffman11@sycamores.indstate.edu); **MICHAEL LODATO**, Evansville, Indiana 47725, USA (e-mail: mikelodato@wowway.com); **TODD PIERSON**, University of Georgia, Athens, Georgia 30602, USA (e-mail: twpierson@gmail.com).

***NOTOPHTHALMUS VIRIDESCENS* (Eastern Newt)**. USA: GEORGIA: Lamar Co.: Milner, Zebulon Road (33.10669°N, 84.21914°W; WGS 84). 1 November 2013. Michael J. Bender. Verified by Gregory D. Hartman, Gordon State College, Vertebrate Collections Manager (GSC-035). New county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens, Georgia. 575 pp.). This species has been documented in three (Monroe, Spalding, and Upson) of the five adjoining counties (Jensen et al. 2008, *op. cit.*). A terrestrial juvenile (eft) was found crossing Zebulon Road ~0.25 km from a large pond during the day (1630 h) following approximately 16 h of intermittent gentle rain. Specimen collected under a Georgia Department of Natural Resources Scientific Collections Permit (29-WJH-13-126).

MICHAEL J. BENDER (e-mail: mbender@gordonstate.edu) and **AMANDA L. J. DUFFUS**, Gordon State College, Barnesville, Georgia 30204, USA (e-mail: aduffus@gordonstate.edu).

ANURA — FROGS

***ACRIS CREPITANS* (Eastern Cricket Frog)**. USA: TENNESSEE: Dyer Co.: Tigrett Wildlife Management Area at the end of Parker Rd. (35.82778°N, 89.26556°W; WGS 84). 17 August 2013. Michael C. Fulbright and James P. Flaherty. Verified by A. Floyd Scott. Austin Peay State University Museum of Zoology (APSU 19437, color photo). New county record (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12, The Center of Excellence for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp. Internet version [http://apbrwww5.apsu.edu/amatlas] accessed 18 August 2013; latest update 1 August 2013)

MICHAEL C. FULBRIGHT (e-mail: mfulbright@my.apsu.edu), **JAMES P. FLAHERTY**, and **C. M. GIENGER**, Center of Excellence for Field Biology/Department of Biology, Austin Peay State University, Clarksville, Tennessee 37040, USA.

***ECNOMIOHYLA MINERA* (Guatemala Treefrog)**. GUATEMALA: HUEHUETENANGO: Barillas: Finca Chiblac, Montaña Los Angeles (15.87341°N, 91.24007°W; WGS 84), 1205 m elev. 20 June 2011. Erick R. López and Timothy A. Herman. Verified by David B. Wake. USAC 3362. First record for Huehuetenango and Sierra de los Cuchumatanes, extending the distribution in Guatemala ca. 133 km W from the nearest documented locality near Purulhá, Baja Verapaz (Global Biodiversity Information Facility 2012. Electronic records for occurrences of *Ecnomiohyla minera*, accessed 20 October 2012 at http://data.gbif.org/species/2428651/). The adult male was found at night following a heavy rainstorm on the trunk of a tree fern (ca. 1 m above ground) alongside a trail in primary cloud forest.

CARLOS R. VÁSQUEZ-ALMAZÁN, Museo de Historia Natural, Universidad de San Carlos de Guatemala, Fundación para el Ecodesarrollo y la Conservación (FUNDAECO), Guatemala City, Guatemala (e-mail: crvasal@yahoo.com.mx); **TIMOTHY A. HERMAN**, Department of Herpetology, Toledo Zoological Society, Toledo, Ohio, USA (e-mail: taherman@gmail.com); **ERICK R. LÓPEZ**, Universidad del Valle de Guatemala, Guatemala City, Guatemala (e-mail: erickrenelo@gmail.com).

***GASTROTHECA PULCHRA* (Marsupial Treefrog)**. BRAZIL: ALAGOAS: Municipality of Murici: Estação Ecológica de Murici

(9.212583°S, 35.879916°W, WGS 84; 533 m elev.) 14 December 2012. B. S. Lisboa, J. V. A. Neto, and I. C. Tiburcio. Setor de Zoologia, Coleção Herpetológica do Museu de História Natural, Universidade Federal de Alagoas, Maceió, Brazil (MUFAL 10829 and 10859 adult females; collecting license ICMBio/SISBIO #33507-1). Verified by F. A. C. Nascimento. This marsupial treefrog is known only from the Brazilian states of Bahia (Caramaschi and Rodrigues 2007. Bol. Mus. Nac. Zool., Rio de Janeiro 525:1–19; Freitas et al. 2009. Herpetol. Rev. 40: 233–234) and Pernambuco (Santos and Santos 2009. Herpetol. Rev. 40:445). First state record, extends the known distribution of the species ca. 53 km S from the closest locality at Private Reserve Frei Caneca, Municipality of Jaqueira, Pernambuco state (Santos and Santos 2009, *op. cit.*) and ca. 865 km N from its type locality at Reserva Biológica de Pau Brasil, Municipality of Porto Seguro, Bahia state (Caramaschi and Rodrigues 2007, *op. cit.*). According to the International Union for Conservation of Nature (IUCN), *G. pulchra* is listed as "Data Deficient," because no information on its population status is available. The presence of this species in a federal conservation unit is significant.

BARNAGLEISON SILVA LISBOA (e-mail: bslgleison@gmail.com), **MIRIAM CAMARGO GUARNIERI**, Programa de Pós-Graduação em Biologia Animal, Centro de Ciências Biológicas, Universidade Federal de Pernambuco, Av. Professor Nelson Chaves, s/n; Cidade Universitária, CEP 50670-420, Recife, PE, Brazil; **TAMÍ MOTT**, Instituto de Ciências Biológicas e da Saúde, Universidade Federal de Alagoas, Av. Lourival Melo Mota, s/n, Tabuleiro, CEP 57072-970 Maceió, AL, Brazil.

***HYALINOBATRACHIUM FLEISCHMANNI* (Fleischmann's Glass Frog)**. EL SALVADOR: MORAZÁN: Municipality of Arambala: Río Sapo Natural Protected Area (13.92896°N, 88.10161°W; WGS84), 665 m elev. 29 September 2012. Vladlen Henríquez and Emanuel Stanley Morán. Verified by William E. Duellman. KUDA 12308–12310. New record for Morazán, extending the species range ca. 25 km S of Marcala, Department of La Paz, Honduras (McCranie and Wilson 2002. The Amphibians of Honduras. SSAR Contrib. Herpetol. 19, Ithaca, New York. x + 625 pp.), and ca. 140 km ESE from the only other known Salvadoran locality at Cantón Montenegro, Santa Ana (Köhler et al. 2006. The Amphibians and Reptiles of El Salvador. Krieger Publ. Co., Malabar, Florida. ix + 238 pp.). The frog was found, along with several calling males, near a slow-moving stream lined with shrubs and trees surrounded by pine-oak forest at the base of the Nahuaterique Mountain Range. It should be noted that we observed many other calling males in the area, located between 665–865 m elevation, along different streams, including one passing through a coffee farm.

VLADLEN HENRÍQUEZ, Colonia Bello San Juan, Calle Madrid, Pol 11. #7, San Salvador, El Salvador (e-mail: vladhen_21@hotmail.com); **ELI GREENBAUM**, Department of Biological Sciences, The University of Texas at El Paso, 500 W. University Ave., El Paso, Texas 79968, USA (e-mail: egreenbaum2@utep.edu).

***LITHOBATES BLAIRI* (Plains Leopard Frog)**. USA: INDIANA: Newton Co.: Iroquois River (40.865464°N, 87.326067°W; WGS 84). 5 October 2013. John Burris, Andrew Hoffman. Verified by Kenneth Krysko. University of Florida (UF-Herpetology 167505, 171192, and 171237 photo vouchers). New county record (Minton 2001. Amphibians and Reptiles of Indiana. Indiana Academy of Science, Indianapolis, xiv + 404 pp.). We observed numerous frogs in rip rap below the bridge and along the vegetated river shoreline. We positively identified three adults as *Lithobates blairi* but Northern Leopard Frogs (*Lithobates pipiens*) were also present.

JOHN BURRIS, 437 N Broad Street, Griffith, Indiana 46319, USA (e-mail: john.burris.jm5s@statefarm.com); **ANDREW HOFFMAN**, Indiana State University, Terre Haute, Indiana 47802, USA (e-mail: ahoffman11@sycamores.indstate.edu).

***LITHOBATES BLAIRI* (Plains Leopard Frog)**. USA: TENNESSEE: Lake Co.: Levee Phillipy Rd. 430 m E of Levee Rd. (36.483543°N, 89.400305°W; WGS 84). 17 August 2013. Michael C. Fulbright and James P. Flaherty. Verified by A. Floyd Scott. Austin Peay State University Museum of Zoology (APSU 19442). This is the first recorded specimen of *Lithobates blairi* in the state of Tennessee (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12, The Center of Excellence for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp. Internet version [http://apbrwww5.apsu.edu/amatlas] accessed 18 August 2013; latest update 1 August 2013) An adult male was caught with a dipnet on the road.

Extensive flooding events in May 2010 and May 2011 may have facilitated the movement of *L. blairi* across the Mississippi River. *Lithobates blairi* was first documented in Fulton Co., Kentucky, on 15 September 2011 (CMC 12314, Cincinnanti Museum of Natural History), and has been subsequently documented in 2012 and 2013 at sites less than a mile north of the Tennessee state line. Our specimen represents the first *L. blairi* in Tennessee. It appears that *L. blairi* readily hybridizes with the established population of *L. sphenocephalus*. We captured 11 *L. blairi* x *L. sphenocephalus* hybrids, and 65 *L. sphenocephalus* while searching for *L. blairi*.

MICHAEL C. FULBRIGHT (e-mail: mfulbright@my.apsu.edu), **JAMES P. FLAHERTY**, and **C. M. GIENGER**, Center of Excellence for Field Biology/Department of Biology, Austin Peay State University, Clarksville, Tennessee 37040, USA; **JON MacGREGOR**, Kentucky Department of Fish and Wildlife Resources, 1 Sportsman's Lane, Frankfort, Kentucky 40601, USA.

***LITHOBATES CATESBEIANUS* (American Bullfrog)**. USA: GEORGIA: Coweta Co.: Senoia (33.3181°N, 84.5935°W; WGS 84). 19 June 2013. Verified by Michael J. Bende. Gordon State College Collection of Vertebrates (GSC 042). New county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens, Georgia. 575 pp.). Specimen collected under a Georgia Department of Natural Resources Scientific Collecting Permit (29-WJH-13-126, CN 25018).

AMANDA L. J. DUFFUS (e-mail: aduffus@gordonstate.edu), **NATALIE B. HAYS** (e-mail: hays_beth@yahoo.com), and **GREGORY D. HARTMAN**, Gordon State College, Barnesville, Georgia 30204, USA (e-mail: ghartman@gordonstate.edu) .

***LITHOBATES CLAMITANS* (Green Frog)**. USA: INDIANA: Putnam Co.: Big Walnut Creek (39.786521°N, 86.779480°W; WGS 84). 27 May 2012. Andrew Hoffman, Sierra Shepard. Verified by Kenneth Krysko. Florida Museum of Natural History (UF-Herpetology 171899 photo voucher); New county record (Minton 2001. Amphibians and Reptiles of Indiana. Indiana Academy of Science, Indianapolis. xiv+ 404 pp.). We found numerous adults and juveniles under rocks along the stream.

ANDREW HOFFMAN, Indiana State University, Terre Haute, Indiana 47802, USA (e-mail: ahoffman11@sycamores.indstate.edu); **SIERRA SHEPARD**, St Mary of the Woods College, Saint Mary of the Woods, Indiana 47876, USA (e-mail: sshepard@smwc.edu).

***LITHOBATES PALUSTRIS* (Pickerel Frog)**. USA: INDIANA: Putnam Co.: Big Walnut Creek (39.786521°N, 86.779480°W; WGS 84).

27 May 2012. Andrew Hoffman, Sierra Shepard. Verified by Kenneth Krysko. Florida Museum of Natural History (UF-Herpetology 171900 photo voucher); New county record (Minton Minton 2001. Amphibians and Reptiles of Indiana. Indiana Academy of Science, Indianapolis, xiv + 404 pp.). We found a single small adult under a rock along the stream.

ANDREW HOFFMAN, Indiana State University, Terre Haute, Indiana 47802, USA (e-mail: ahoffman11@sycamores.indstate.edu); **SIERRA SHEPARD**, St Mary of the Woods College, Saint Mary of the Woods, Indiana 47876, USA (e-mail: sshepard@smwc.edu).

***LITHOBATES SPHENOCEPHALUS* (Southern Leopard Frog)** USA: GEORGIA: Lamar Co.: Barnesville, Highway 18 (33.03123°N, 84.18795°W; WGS 84). 6 June 2013. Austin Dean and Ashley Dean. Verified by Gregory D. Hartman. Gordon State College Collection of Vertebrates (GSC 041). New county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens, Georgia. 575 pp.). Three juveniles. Specimens collected under a Georgia Department of Natural Resources Scientific Collecting Permit (29-WJH-13-126, CN 25018).

AMANDA L. J. DUFFUS (e-mail: aduffus@gordonstate.edu), **ASHLEY DEAN** (e-mail: ad077078@gordonstate.edu), **AUSTIN DEAN** (e-mail: abacer86@hotmail.com), and **MICHAEL J. BENDER**, Gordon State College, Barnesville, Georgia 30204, USA (e-mail: mbender@gordonstate.edu).

***RHINELLA AZARAI* (Azara's Granulated Toad)**. BRAZIL: MATO GROSSO DO SUL: Municipality of Rio Brilhante: Wetland adjacent to the Brilhante River (21.898638°S, 54.029526°W; datum WGS 84). 8 October 2013. F. I. Martins and B. F. Leonel. Coleção Zoológica de Referência da Universidade Federal de Mato Grosso do Sul, Brazil (ZUFMS AMP 03268, male SVL 49 mm, calling at 1900 h in a temporal pond). Verified by F. L. Souza. *Rhinella azarai* is known from northern Argentina, Paraguay, and southwestern Brazil, with most occurrences associated with Chaco lowlands (Narvaes and Rodrigues 2009. Arq. Zool., S. Paulo 40[1]:1–73). In Brazil there are only three reports of the species, all in municipalities of Mato Grosso do Sul state: Bela Vista, Maracajú (Narvaes and Rodrigues 2009, *op. cit.*) and Porto Murtinho (Sugai et al. 2012. Herpetol. Rev. 43[3]:441). The present record extends the species distribution ca. 120 km SE from municipality of Maracajú (21.63333°S, 55.150000°W), the nearest locality previously known, and it is the first report of *R. azarai* in the ecoregion of Alto Paraná Atlantic Forest (Di Bitetti et al. 2003. Uma Visão de Biodiversidade para a Ecorregião Florestas do Alto Paraná: Mata Atlântica. World Wildlife Fund., Washington, D.C. 152 pp.).

SUGAI** (e-mail: jlmassao@gmail.com), **BRENO FRANCO LEONEL** (e-mail: brenoleonel@gmail.com), and **SABINE BORGES DA ROCHA** (e-mail: sabineborges@hotmail.com), Programa de Pós-graduação em Biologia Animal, 79070-900, Campo Grande, MS, Brazil.

***SCAPHIOPUS HOLBROOKII* (Eastern Spadefoot)**. USA: TENNESSEE: Washington Co.: Liberty Church Road (36.1420°N, 82.6158°W; WGS 84). Scott and Christopher Bolick. Verified by A. Floyd Scott. APSU 19450. New county record (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12, The Center of Excellence for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp. [Hard copy and Internet versions, http://apbrwww5.apsu.edu/amatlas/index.html, accessed 11 September 2013]). Two other localities within the county were also identified (ASPU 19451, 19452). All specimens found alive on roads.

SCOTT BOLICK, 379 Cassi Rd., Chuckey, Tennessee 37641, USA (e-mail: Bolickscott@yahoo.com); **CHRISTOPHER BOLICK**, Catawba College, 2300 W Innes St, Salisbury, North Carolina 28144, USA (e-mail: cwbolick@catawba.edu).

***ZAKERANA PIERREI* (Pierre's Cricket Frog)**. BANGLADESH: RANGPUR DISTRICT: New Adarsha Para, Rangpur City (25.738652°N, 89.25375°E, WGS 84; 34 m elev.). 7 August 2013. Hassan-Al-Razi. Verified by Mohammad Sajid Ali Howlader. Museum of Zoology Laboratory, Jagannath University, Bangladesh (MZJLB-FP01). Adult collected beside a small water body, including *Cynodon dactylon* and *Enhydra fluetuans* plantations. Previously recorded from Nilphamari District (Sarker and Howlader 2011. Herpetol. Rev. 42[4]:562), and Chittagong (Hathazari), Cox's Bazar (Himchari), Noakhali (Hatia Island), and Barisal (Sundargaon), southeast Bangladesh (Rasel et al. 2007. Bannoprani- Bangladesh Wildl. Bull. 4:1–2). Present population found near New Adarsha Para, Rangpur City, Adarsha High School, > 50 km E from Nilphamari District and > 448 km NW of Chittagong (Hathazari), < 565 km NW of Cox's Bazaar (Himchari), < 490 km NW of Noakhali (Hatia Island), and < 356 km NW for Barisal (Sundargaon).

HASSAN-AL-RAZI (e-mail: chayan1999@yahoo.com), and **MD. MOMIN MEHEDI SELIM** (e-mail: selim2801@yahoo.com), Department of Zoology Jagannath University, Dhaka and Herpetology Laboratory Bangladesh, Society for Research and Development, House No. E-23, Floor-5A, Road-02, Block-D, Bashundhara R/A, Dhaka 1229, Bangladesh.

TESTUDINES — TURTLES

***APALONE MUTICA* (Smooth Softshell)**. USA: NEBRASKA: Boyd Co.: Mile 869.4 of the Missouri River (42.93563°N, 98.45551°W; WGS 84). 18 September 2012. Ryan J. Munes. Verified by Travis J. LaDuc. Texas Natural History Collections (TNHC 86195). New county record (Ballinger et al. 2010. Amphibians and Reptiles of Nebraska. Rusty Lizard Press, Oro Valley, Arizona. 400 pp.; Fogell 2010. A Field Guide to the Amphibians and Reptiles of Nebraska. University of Nebraska-Lincoln, Lincoln, Nebraska. 158 pp.). Previous records exist to the east in Knox Co. and to the west in Keya Paha Co. Hatchling found dead on sandbar in river. Specimen collected under a Nebraska Game and Parks Commission Scientific and Educational Permit (# 293) to Drew R. Davis.

RYAN J. MUNES (e-mail: rjmunes@gmail.com) and **DREW R. DAVIS,** Department of Biology, University of South Dakota, 414 East Clark Street, Vermillion, South Dakota 57069, USA (e-mail: drew.davis@usd.edu).

***APALONE SPINIFERA* (Spiny Softshell)** USA: GEORGIA: Fayette Co.: Peachtree City (33.3972°N, 84.5628°W; WGS 84). 25 June 2013. Tiffany Ward. Verified by Michael J. Bender. Gordon State College Collection of Vertebrates (GSC 047). New county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens, Georgia. 575 pp.). Adult turtle from Huddleson Pond. Specimen collected under a Georgia Department of Natural Resources Scientific Collecting Permit (29-WJH-13-126, CN 25018).

AMANDA L. J. DUFFUS (e-mail: aduffus@gordonstate.edu), **TIFFANY M. WARD** (e-mail ward.tiffany1281@gmail.com), and **GREGORY D. HARTMAN**, Gordon State College, Barnesville, Georgia 30204, USA (e-mail: ghartman@gordonstate.edu).

***APALONE SPINIFERA* (Spiny Softshell)**. USA: INDIANA: Franklin Co.: Whitewater River (39.378934°N, 84.973001°W; WGS 84).

27 July 2011. Andrew Hoffman, Sierra Shepard. Florida Museum of Natural History (UF-Herpetology 171910 photo voucher). New county record (Minton 2001. Amphibians and Reptiles of Indiana. Indiana Academy of Science, Indianapolis. xvi + 404 pp.). A single juvenile was photographed swimming through the shallows. Numerous adults were observed along the river throughout the day.

Putnam Co.: Big Walnut Creek (39.785007°N, 86.778656°W; WGS 84). 27 May 2012. Andrew Hoffman, Sierra Shepard. UF-Herpetology 171898 photo voucher. New county record (Minton 2001, *op. cit.*). A large adult female buried in a very small, but deep patch of sand, below a small riffle, in the shallows of a stream. All records verified by Kenneth Krysko.

ANDREW HOFFMAN, Indiana State University, Terre Haute, Indiana, 47802, USA (e-mail: ahoffman11@sycamores.indstate.edu); and **SIERRA SHEPARD**, St Mary of the Woods College, Saint Mary of the Woods, Indiana, 47876,USA (e-mail: sshepard@smwc.edu).

***CHELONIA MYDAS* (Green Sea Turtle)**. USA: LOUSIANA: Cameron Parish: Salt marsh 100 m S of Louisiana Hwy 82 and 1 km E of Texas-Louisiana border (29.76746°N, 93.88262°W; WGS84). 25 April 2013, 1300 h. Will Selman and Ryan King. Florida Museum of Natural History Herpetology Department (UF 170048, photo voucher). First verified record from southwestern Louisiana (Dundee and Rossman 1989. The Amphibians and Reptiles of Louisiana. Louisiana State University Press, Baton Rouge and London. 300 pp.; HerpNet collections database, www.herpnet2.org, accessed 28 October 2013). A putative skeletal record of *C. mydas* from Cameron Parish exists in the LSU-Shreveport collection (LSUS 8456) from a dead individual that washed onto the beach from offshore. However, based upon the skeletal material available, the specimen cannot be verified to species (J. Boundy, pers. comm.). Juvenile (27.3 cm midline carapace length [MCL]; 2700 g) captured in a salt marsh.

St. Bernard Parish: Salt marsh on the fringe of Eloi Bay approximately 23.3 km ESE of Hopedale, Louisiana (29.78886°N, 89.41930°W; WGS84). 15 May 2013. Dane Cassady and Amy Magro. UF Herpetology 171444 (photo voucher). New parish record (Dundee and Rossman, *op. cit.*; HerpNet collections database, www.herpnet2.org, accessed 28 October 2013). This record fills the distributional gap that existed between an Orleans Parish specimen (near New Orleans, USNM 55569) and a Plaquemines Parish specimen (Breton Island, unpublished literature record cited by Dundee and Rossman, *op. cit.*). Juvenile (approx. 30 cm MCL) captured in salt marsh

Terrebonne Parish: Salt marsh 2.3 km NE of Cocodrie, Louisiana at the north end of Bay Cocodrie (29.26237°N, 90.64619°W; WGS84). 16 May 2013. Ben Stultz and Todd Credeur. UF Herpetology 171449 (photo voucher). New parish record (Dundee and Rossman, *op. cit.*; HerpNet collections database, www.herpnet2.org, accessed 28 October 2013). This record is 70 km W of a Jefferson Parish specimen collected in 1962 on Grand Terre Island (LSU Herpetology 54213). This animal was a juvenile (approx. 22 cm MCL).

All individuals were captured alive in fyke nets, which were placed in tidal bayous while conducting *Malaclemys terrapin* (Diamondback Terrapin) surveys. Trap locations ranged between 0.8–1.4 m deep and 7.6–14 m wide, while water salinities ranged between 5.6–16 ppt and water temperature ranged between 22.3–24°C. Following species documentation and measurements, all individuals were released at the capture site. All photo vouchers were verified by Jeff Boundy.

It seems beyond a coincidence that all three individuals were juveniles of similar size, captured in similar salt/brackish marsh habitat, and all captured within a span of 21 days. Dundee and Rossman (*op. cit.*) considered *C. mydas* a "visitor" to Louisiana. However, Fuller et al. (1987. Sea Turtles in Louisiana Coastal Waters. Report for the Coastal Fisheries Institute and Louisiana Sea Grant College Program. Baton Rouge, Louisiana. 39 pp. with appendix) noted that *C. mydas* is the second most observed species by fishermen/marine-oriented people in Louisiana, with most reports being juveniles in the southeastern portion of the state. Because we cannot determine the validity of the self reported records in Fuller et al. (*op. cit.*), we consider our records from Terrebonne and St. Bernard parishes the first verifiable *C. mydas* records for these parishes. Based on the three individuals reported herein, juvenile *C. mydas* appear to be seasonally utilizing near shore habitats during the late spring and early summer in Louisiana. The sizes we report are also consistent with the estimation that *C. mydas* juveniles leave the "oceanic" stage around 25–35 cm MCL (Reich et al. 2007. Biol. Letters 3:712–714). Because juveniles are more carnivorous than adults (Ernst and Lovich 2009. Turtles of the United States and Canada, 2nd ed. Johns Hopkins Press, Baltimore, Maryland. 827 pp.), it is possible that they are consuming marine invertebrates in salt and brackish marsh habitats.

We thank Steven Pearson for assistance and review of the note.

WILL SELMAN (e-mail: wselman@wlf.la.gov) and **RYAN KING**, Rockefeller Wildlife Refuge, Louisiana Department of Wildlife and Fisheries, 5476 Grand Chenier Hwy, Grand Chenier, Louisiana 70643, USA; **BENJAMIN STULTZ**, Louisiana Department of Wildlife and Fisheries, 5652 Hwy 182, Opelousas, Louisiana 70570, USA; **DANE CASSADY**, 2018 Shady Grove Way, Louisville, Kentucky 40218, USA; **AMY MAGRO**, **TODD CREDEUR**, and **JON J. ***CHRYSEMYS DORSALIS* (Southern Painted Turtle)**. USA: TENNESSEE: Weakley Co.: Greenfield (36.193055°N, 88.762222°W; NAD 83). 18 August 2013. James P. Flaherty and Michael C. Fulbright. Verified by A. Floyd Scott. Austin Peay State University Museum of Zoology (APSU 19444). New county record (Scott and Redmond 2008 (latest update: 7 August 2013). Atlas of Reptiles in Tennessee. The Center of Excellence for Field Biology, Austin Peay State University, Clarksville, Tennessee. Available at http://apsu.edu/reptatlas/ [accessed 6 September 2013]). Nearest record ca. 26 km distant in Carroll Co. Found dead on road.

JAMES P. FLAHERTY (e-mail: jflaherty1@my.apsu.edu), **MICHAEL C. FULBRIGHT**, and **C. M. GIENGER**, Center of Excellence for Field Biology/Department of Biology, Austin Peay State University, Clarksville, Tennessee 37040, USA

***CHRYSEMYS PICTA* (Painted Turtle)**. USA: FLORIDA: Volusia Co.: Blue Springs State Park, 96 m E of the mouth of St. Johns River inside of the Blue Spring Run (28.94345°N, 81.34102°W, WGS84; elev. 6 m). 4 October 2013. Eric C. Munscher. Verified by Kenneth L. Krysko. Photos and specimen deposited in the Florida Museum of Natural History (UF 171291). New county record (Krysko et al. 2011. Atlas of Amphibians and Reptiles in Florida. Final Report, Florida Fish and Wildlife Conservation Commission, Tallahassee, Florida. 524 pp.). Female (carapace length = 247 mm, plastron length = 183 mm, mass = 1568 g) captured by hand at 1000 h along the right side of the lower Blue Spring Run toward the St. Johns River. The lack of algae on the carapace

suggests this is a recently released captive pet turtle. This is the first reported occurrence of *Chrysemys picta* in the St. Johns River Basin and only one of several reported within the state. This non-indigenous species is relatively common in the pet trade. At this point we highly doubt there is a mass introduction of this species and expect that this was an isolated incident of someone releasing their pet turtle. Exotic reptiles have been commonly sold in pet stores in Florida for decades. Species such as the Red-eared Slider (*Trachemys scripta elegans*) have been able to establish potential breeding populations and may compete or hybridize with native species.

SQUAMATA — LIZARDS

***ANADIA OCELLATA* (Ocellated Anadia)**. REPUBLIC OF PANAMA: VERAGUAS: Santa Fe District: Escobal River (8.54511°N, 81.11978°W; WGS84), 432 m elev. 23 September 2011. E. E. Flores. Verified by Gunther Köhler. MVUP 2094. This report confirms a 1980 record for Veraguas Province (AMNH 147802) that lacked exact locality information, and is also the first record for the Santa Fe National Park, located in Panama's central cordillera region (Köhler 2008. Reptiles of Central America, 2nd ed. Herpeton, Verlag Elke Köhler, Offenbach, Germany. 400 pp.). The specimen was captured at 1240 h while active on rocks forming a small islet near the river's shore, which represents a new reported habitat for the species; prior reports indicated that it typically occupies tree canopies (Savage 2005. The Amphibians and Reptiles of Costa Rica: A Herpetofauna Between Two Continents, Between Two Seas. Univ. Chicago Press, Chicago, Illinois. 954 pp.). This work was conducted under the scientific permit (SA/E-62-11) provided by the Panamanian National Authority for the Environment (ANAM).

***ANOLIS SAGREI* (Brown Anole; Abaniquillo Costero)**. HONDURAS: ISLAS DE LA BAHÍA: Isla de Utila, Utila Town (16.083602°N, 86.883486°W; WGS84). 10 m elev. 24 April 2012. Sofia Nuñez. Verified by Gustavo A. Cruz. UNAH 5567–68. First records for Isla de Utila; previously known on Islas de la Bahía only from Isla de Roatán (McCranie et al. 2005. The Amphibians & Reptiles of the Bay Islands and Cayos Cochinos, Honduras. Bibliomania!, Salt Lake City, Utah. xiii + 210 pp.). The closest known locality on Roatán to our record is ca. 45 km NE at Coxen Hole. The anoles were found on a tree branch at 0900 h.

JAMES R. McCRANIE, 10770 SW 164th Street, Miami, Florida 33157–2933, USA (e-mail: jmccrani@bellsouth.net); **SOFIA NUÑEZ**, Tegucigalpa, Main Street, Bloque U-26, Distrito Central, Honduras (e-mail: biopopia@yahool.com).

***ANOLIS SAGREI* (Brown Anole)**. USA: TEXAS: Matagorda Co.: Courtyard wall of Matagorda Regional Medical Center approximately 2.1 km W of the historic square of Bay City (28.97993°N, 95.99204°W; WGS 84). 22 July 2013. Christian L. Swanson. Verified by Travis LaDuc. TNHC 85948. First documented occurrence of the species within Matagorda Co. (Dixon 2013. Amphibians and Reptiles of Texas: with Keys, Taxonomic Synopses, Bibliography, and Distribution Maps. Texas A&M University Press, College Station. 447 pp.). Several (>5) individuals were observed within proximity of the moist, partially shaded courtyard. The presence of *Anolis sagrei* has been documented within counties surrounding important Texas ports and occasionally further inland. This stratified distribution confirms human mediation within Texas and provides an anecdotal predictor for the potential of ongoing colonization. Matagorda Co. is bordered to the east by a cluster of counties (Brazoria, Fort Bend, Galveston, and Harris) where the presence of *A. sagrei* has been previously confirmed.

CHRISTIAN L. SWANSON, **ROMEY L. SWANSON** (e-mail: romeyswanson@gmail.com), and **J. ERIC LEE**, New Braunfels, Texas 78130, USA (e-mail: ericlee@balconeswildlife.com).

***CHALCIDES OCELLATUS* (Ocellated Skink)**. GREECE: SOUTH AEGEAN.: Syros Island, Galissa Bay (37.413856°N, 24.878516°E; WGS 84; 68 m elev.). 10 September 2013. Stephanos A. Roussos and Llewellyn D. Densmore III. Verified by A. Dimitropoulos, M. Dimaki, J. Foufopoulos and P. Lymberakis. Natural History Museum of Crete (NHMC 80.3.80.1127–1130) and University of Michigan Museum of Zoology, Division of Reptiles and Amphibians (Digital Image Collection Number 1228, photographic voucher, one individual). New island record (Chondropoulos 1986. Amphibia-Reptilia 3:217–235). This represents a rare find in the prefecture of the Cyclades as it had only been documented on the islands of Makronissos and Kea (Tzia) (Chondropoulos 1986, *op. cit.*), which are the closest Cycladic islands to the mainland where the species is common. Makronissos and Kea differ from the rest of the archipelago in that they were connected to the mainland fairly recently (10,000 years ago) compared to the other Cycladic islands and thus share different geological histories. The species was recently documented for the first time on the Cycladic island of Naxos (Belasen et al. 2012. Herpetol. Rev. 43:102), which was part of an ancient "super" island that separated from the mainland about 200,000 years ago and then fragmented following the last glaciation (18,000 years ago) into more than 20 islands that make up a large portion of the archipelago. Syros is also one of the islands that fragmented from this ancient "super" island. Seven specimens were found by SAR in 2011 on the northern slopes of Mt. Harasonas, south of Galissa Bay, under rocks, leaf litter, tin, and cement blocks but photo vouchers from these individuals were inadvertently lost. The same site was revisited in 2013 where 17 individuals were found in two hours mid-day (see above for specimen references). Both adults and juveniles were found, indicating a healthy population at this locality.

STEPHANOS A. ROUSSOS (e-mail: sa.roussos@ttu.edu), and **LLEWELLYN D. DENSMORE III,** Department of Biological Sciences, MS 43131, Texas Tech University, Lubbock, Texas 79409-3131, USA.

***EREMIASCINCUS ISOLEPIS* (Northern Bar-lipped Skink)**. AUSTRALIA: WESTERN AUSTRALIA: Forrester Bay, 87 km E of Karratha (20.66944°S, 117.6825°E; WGS84). 3 December 2012. Ryan Ellis and Sean Doody. Western Australian Museum (WAM R173016, R173018). Verified by Paul Doughty (WAM). Multiple individuals caught in pit traps and funnel traps during faunal survey, two specimens collected and vouchered. Most northeasterly record for the geographically isolated Pilbara population, located approximately 400 km SW of the nearest verified record in the Kimberley population. The two populations may represent different species; however, further work is required to confirm this. This record extends the known range of the Pilbara population 70 km NE along the coastline from the nearest verified locality

near Lake Poongkaliyarra (R135280), south of Roebourne (WAM herpetofauna specimen database, accessed 8 August 2013). The WAM herpetofauna specimen database was accessed to identify the locations of the nearest confirmed specimens in the collection and confirm that those collected represented a distribution extension for the species. An additional search was made in OZCAM (Online Zoological Collections of Australian Museums; http://ozcam.org.au/, accessed 8 August 2013).

RYAN J. ELLIS, Department of Terrestrial Zoology, Western Australian Museum, 49 Kew Street, Welshpool, Western Australia, 6106, Australia (e-mail: Ryan.Ellis@museum.wa.gov.au); **J. ***HEMIDACTYLUS TURCICUS* (Mediterranean Gecko)** USA: GEORGIA: Bibb Co.: Macon, Hillcrest Industrial Boulevard, between Roff Avenue and Hillcrest Avenue (32.84374°N, 83.67290°W; WGS 84). 4 June 2013. Austin Dean and Ashley Dean. Verified by Gregory D. Hartman. Gordon State College Collection of Vertebrates (GSC 036). New county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens, Georgia. 575 pp.). An adult with a partially regrown tail captured inside a non-climate-controlled, lighted storage warehouse. There appears to be a small population of this introduced species. Specimen collected under a Georgia Department of Natural Resources Scientific Collecting Permit (29-WJH-13-126, CN 25018).

AMANDA L. J. DUFFUS (e-mail: aduffus@gordonstate.edu) and **ASHLEY DEAN**, Gordon State College, Barnesville, Georgia 30204, USA (e-mail: ad077078@gordonstate.edu); and **AUSTIN DEAN** (e-mail: abacer86@hotmail.com).

***HEMIDACTYLUS TURCICUS* (Mediterranean Gecko)**. USA: VIRGINIA: Montgomery Co.: Blacksburg, Derring Hall, Virginia Tech campus (37.229320°N, 80.425633°W, WGS 84). 7 May 2013. Meredith Swartwout. Verified by Robin Andrews. Virginia Museum of Natural History (VMNH 150014). First documented voucher specimen for the county. *Hemidactylus turcicus* has been recorded in Virginia from Richmond, Lynchburg, and Bedford counties (Sattler et al. 2007. Catesbeiana 27[1]: http://www.virginiaherpetologicalsociety.com/reptiles/lizards/mediterranean-gecko/Mediterranean%20Gecko.pdf). Knight (1993. Dactylus 2:49–50) reported *H. turcicus* from the Virginia Tech campus, but did not collect voucher specimens.

A small population of *H. turcicus* was accidentally released in the Virginia Tech Department of Biological Sciences building, Derring Hall, in 1982 (R. Andrews, pers. comm.). Since then, about six or seven sightings (adults and hatchlings) have been reported from the building each year. The voucher specimen captured on 7 May 2013 was an adult *H. turcicus* that was living in one of the animal care rooms. Temperature-controlled animal care rooms and maintenance areas in the building may serve as refuges for these geckos. Knight (1993, *op. cit.*) suggested that the steam tunnels could also support a population of *H. turcicus*, but to this date there have been no reported gecko sightings from the steam tunnels by workers (D. Linzey, pers. obs.)

MEREDITH C. SWARTWOUT (e-mail: mswart17@vt.edu), **ROBIN ANDREWS** (e-mail: randrews@vt.edu), Virginia Tech, Department of Biological Sciences, Blacksburg, Virginia 24061, USA; **DONALD LINZEY,** Virginia Tech, Department of Fish and Wildlife Conservation, Blacksburg, Virginia 24061, USA (e-mail: dlinzey@vt.edu).

***LEPOSTERNON POLYSTEGUM* (Bahia Worm Lizard)**. BRAZIL: PARAÍBA: Municipality of São José de Piranhas: 7.146°S, 38.601°W; WGS84). 14 November 2012. Wildlife Rescue Team from the Project of Integration of São Francisco river (PISF) with the basins of septentrional northeastern. Coleção de Herpetologia do Museu de Fauna da Caatinga, Centro de Conservação e Manejo de Fauna da Caatinga – Universidade Federal do Vale do São Francisco, Petrolina, Pernambuco, Brazil (MFCH 2418). Verified by M. T. Rodrigues. Species previously known from the following Brazilian states: Pará (Belém municipality); Maranhão (municipalities of Igarapé Grande, Santa Luzia do Paruá and locality of Paraquéu); Ceará (Planalto da Ibiapaba: municipalities of Ibiapina, São Benedito, Tinguá and Ubajara; Serra de Maranguape: Maranguape municipality; Serra da Aratanha: Pacatuba municipality; Chapada do Araripe: municipalities of Crato (Floresta Nacional do Araripe) and Barbalha); coastal zones of Rio Grande do Norte and Pernambuco; Alagoas (Piranhas municipality); Bahia (municipalities of Feira de Santana, São Gonçalo dos Campos, Xique-Xique and Casa Nova) and Tocantins (Jalapão microrregion and Lajeado municipality) (Rodrigues 1996. J. Herpetol. 30:513–523; Barros-Filho and Valverde 1996. Sitientibus 14:57–68; Borges-Nojosa and Caramaschi 2005. *In* Leal et al. [eds.], Ecologia e Conservação da Caatinga, pp. 463–512. Ed. Universitária UFPE, Brazil; Perez and Ribeiro 2008. Check List 4:291–294). First state record, extends the distribution ca. 90 km NE from the municipality of Barbalha, state of Ceará, Brazil. We also collected specimens of *L. polystegum* in additional municipalities in the states of Ceará (Brejo Santo and Mauriti), and Pernambuco (Cabrobó, Floresta, Custódia and Sertânia).

Collecting permit was issued by Instituto Brasileiro do Meio Ambiente e dos Recursos Naturais Renováveis (IBAMA) (# 95/2012, process nº 02001.003718/94-54); field work supported by Ministério da Integração Nacional.

***TROPIDOPHORUS THAI* (Thai Water Skink)**. THAILAND: LOEI PROVINCE: Phu Rue District: Phu Luang Wildlife Sanctuary, Phu Luang Wildlife Research Station (17.342965°N, 101.508783°E, WGS 84; ca. 980 m elev.). Khon Kaen University Vertebrate Collection (KKUD 2013.3a–g). Y. Chuaynkern (KKUD 2013.3a) and Attapol Rujirawan (KKUD 2013.3b–g). 20 October 2013. Verified by Sunchai Makchai. Under rock on bank of artificial reservoir during day. Adult male, SVL 86.3 mm, TL 65.3 mm (tail regenerated), head width 9.7 mm. Scale row at mid-body 34; other morphological characteristics fit description and identification key (Taylor 1963. Univ. Kansas Sci. Bull. 44:687–1077). Released after examination and photography. First provincial record for Loei Province and first record for NE Thailand, ca. 325 km SE of previous nearest locality ("Pa Meang, Me Wang District," Chiang Mai Province; Taylor 1963, *op. cit.*). Previously known from northern Thailand, in Chiang Mai and Mae Hong Son provinces (Chuaynkern and Chuaynkern 2012. J. Wildl. Thailand 19:75–162).

We were supported by grants from Faculty of Science (Khon Kaen University) to YC. We thank our institutions, the Department of National Park, Wildlife and Plants, Khon Kaen University and Kasetsart University, for supporting this work.

YODCHAIY CHUAYNKERN (e-mail: yodchaiy@kku.ac.th) and **CHANTIP CHUAYNKERN** (e-mail: ichant@kku.ac.th), Department of Biology, Faculty of Science, Khon Kaen University, Muang, Khon Kaen 40002, Thailand; **JIRACHAI ARKAJAG** and **STAPHON TONGPUN**, Phu Luang Wildlife Research Station, P.O. Box 10, Phu Rue, Loei, 42160, Thailand; **PRATEEP DUENGKAE**, Department of Forest Biology, Faculty of Forestry, Kasetsart University, Jatujak, Bangkok 10900, Thailand, and the Center for Advanced Studies in Tropical Natural Resources, Kasetsart University, Jatujak, Bangkok, Thailand (e-mail: prateep.du@ku.ac.th).

***TROPIDURUS HISPIDUS* (Peters' Lava Lizard)**. BRAZIL: AMAPÁ: Municipality of Macapá: Campus da Universidade Federal do Amapá (0.006111°N, 51.0825°W; datum WGS84). 26 September 2011. Verified by T. C. S. Ávila-Pires. Collection of the Universidade Federal do Amapá – UNIFAP, Macapá, Brazil (CDLABZOO 111, Chico Mendes Institute for Biodiversity Conservation permission number 31814-2). This species is a widely distributed neotropical lizard, occurring from northeast Brazil in eastern limit in the state of Maranhao, north of the Amazon River (state of Para), central Amazon (state of Amazonas), southern part of French Guiana, Suriname, Guyana, and Venezuela (Ávila-Pires 1995. Zool. Verh. Leiden. 299:1–706). First state record, partially filling the gap between French Guiana and Pará by about 225 km to the northwest.

NAZIEL SANTOS SOUZA, Laboratório de Zoologia, Universidade Federal do Amapá (e-mail: souzanaziel@gmail.com) and **CARLOS EDUARDO COSTA CAMPOS**, Departamento Ciências Biológicas e da Saúde, Universidade Federal do Amapá, Laboratório de Zoologia, Campus Marco Zero CEP 68903-280, Macapá, AP, Brazil (e-mail: eduardocampos@unifap.br).

***UROSAURUS GRACIOSUS* (Long-tailed Brush Lizard)**. USA: ARIZONA: Maricopa Co.: Hummingbird Spring Wilderness (33.589°N, 113.059°W; NAD 83; elev. 484 m). 13 August 2013. Keith Sullivan and Hunter McCall. Verified by Brian K. Sullivan (Museum of Vertebrate Zoology observation [MVZ obs Herp # 15 photo voucher]). This specimen extends the range 56 km SW of the nearest locality, Wickenburg, Arizona (Brennan and Holycross 2006. A Field Guide to Amphibians and Reptiles in Arizona. Arizona Game and Fish Department, Phoenix. v + 150 pp.). Reduces the apparent gap within the distribution of this lizard in western Arizona. The lizard (and others observed by the authors at this site) was 2 m off the ground in an Ironwood Tree (*Olynea tesota*) in a rocky, upland habitat rather than in a sandy riparian corridor more typically frequented by this species elsewhere in central Arizona. The specimen possessed uniformly enlarged scales over the dorsal mid-line, and a tail length over twice the snout–vent length.

KEITH SULLIVAN (e-mail: kosullivan@azgfd.gov), and **HUNTER McCALL**, Contracts Branch, Arizona Game and Fish Department, Phoenix, Arizona 85086, USA.

SQUAMATA — SNAKES

***AGKISTRODON CONTORTRIX* (Copperhead)**. USA: GEORGIA: Lamar Co.: Grape Creek Road in Milner (33.10766°N, 84.22294°W; WGS 84). 30 October 2013. Michael J. Bender. Verified by Gregory D. Hartman, Gordon State College Vertebrate Collections (GSC 034). New county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens, Georgia. 575 pp.). This species has been documented in three (Monroe, Spalding, and Upson) of the five adjoining counties (Jensen et al. 2008, *op. cit.*). Specimen collected under a Georgia Department of Natural Resources Scientific Collections Permit (29-WJH-13-126).

MICHAEL J. BENDER (e-mail: mbender@gordonstate.edu), and **AMANDA L. J. DUFFUS,** Gordon State College, Barnesville, Georgia 30204, USA (e-mail: aduffus@gordonstate.edu).

***AGKISTRODON CONTORTRIX* (Copperhead)**. USA: TENNESSEE: Gibson Co.: Milan Army Ammunition Plant (35.855833°N, 88.721388°W; NAD 83). 8 August 2013. James P. Flaherty, Michael C. Fulbright, Shawn P. Settle, and Aaron T. Ross. Verified by A. Floyd Scott. Austin Peay State University Museum of Zoology (APSU 19449). First vouchered record for county (Scott and Redmond 2008 [latest update: 30 May 2013]. Atlas of Reptiles in Tennessee. The Center of Excellence for Field Biology, Austin Peay State University, Clarksville, Tennessee. Available at http://apsu.edu/reptatlas/ [accessed 6 September 2013]).

***NERODIA CLARKII* (Gulf Salt Marsh Snake)**. USA: LOUISIANA: Tangipahoa Parish: Manchac Land Bridge Area (30.24°N, 90.40°W; WGS84). 7 September 2012. Logan D. McCardle, Anthony Haase, and Clifford L. Fontenot. Verified by Brian I. Crother. Southeastern Louisiana University Department of Biological Sciences Vertebrate Museum (SLU 01042). New parish record (Dundee and Rossman 1996. The Amphibians and Reptiles of Louisiana. Louisiana State University Press, Baton Rouge Louisiana).

After the flooding from Hurricane Isaac (August 2012) subsided, we collected three individuals of *Nerodia clarkii* (SLU 01042, 01043, and a juvenile) on U.S. Highway 51, approximately 16.7 km S of the junction between Interstate 55 near the town of Ponchatoula. Three additional specimens were collected during surveys in 2013, but were not preserved because of poor condition. These snakes were encountered during weekly sampling, as part of a snake assemblage monitoring road survey that has been ongoing for 10 years (2003–2013) along a 37-km segment of U.S. Highway 51, the Manchac Land Bridge Area, which transects the wetland that divides Lakes Pontchartrain and Maurepas. All specimens of *N. clarkii* were collected within 10 months following Hurricane Isaac.

There is a known deme of *N. clarkii* in Fontainebleau State Park in St. Tammany Parish approximately 30 km from where these individuals were collected, as well as others much farther south along the Gulf Coast. The appearance of these individuals in the Manchac Land Bridge Area (MLBA) is likely an artifact of record flooding that occurred in the area caused by storm surge and heavy rain events associated with Hurricane Isaac. Such storms often produce sustained east and south wind for several days, which drives water from the Gulf of Mexico westward through Lake Borgne, the Rigolets, Lake Pontchartrain, Pass Manchac, and into Lake Maurepas. The MLBA is normally dominated by fresh water marsh habitat with dynamic elevation gradients throughout. During our study, peak numbers of snakes collected on the road often followed flood events. The maximum elevation gradient in this marsh is 1.5 m; flooding events that exceed this cause snakes to seek refuge in the roadway.

Finding multiple individuals of this species immediately following a heavy flooding event suggests that such disturbances are possible mechanisms of dispersal, and that such events have likely occurred in the past. Because *N. clarkii* is typically associated with brackish marsh, its salinity preferences and other aspects of its ecology may have constrained past founders from establishing viable populations in the fresh marsh of the MLBA. However, salinity of the MBLA is increasing, and projected to continue increasing in the near future.

A Herpetofaunal Survey of Pike County, Alabama, USA

Recent examinations of historical and current records for Pike Co., Alabama, USA, indicate that there are 35 amphibian and reptile species that have never been accounted for in the county but that might otherwise be expected to occur there (Mount 1975). Of species known to occur in Pike Co., 16 are listed as moderate conservation concern, six species as high conservation concern, and two as highest conservation concern (Alabama Natural Heritage Program 2011). A systematic program of field observation of amphibians and reptiles in Pike Co. started with the field vertebrate zoology course at Troy University, and will continue on public lands with diverse habitats. Pike Co., Alabama is located in the southeastern section of the state, and has a total area of ca. 1740 km^2 or 174,128 hectares (USDA 1997), including the Pocosin Forever Wild Tract.

To obtain an estimate of the herpetological diversity in the county, all major habitats were sampled following all professional and state guidelines for observation, capture, and/or release. Weekly collections (if applicable) and observations were made each month from January through December. Documentation of any observed herpetological specimens include photographs and notes regarding surrounding habitat, specific GPS location of collecting site, the number of specimens observed and/or collected, and sampling methodology (handling procedure). The datum for all GPS coordinates is WGS 84.

With the assistance of Auburn University, records were vouchered as specimens or digital photographs, and deposited in the Troy University Zoological Collections and in the Herpetological Collections of Auburn University. All records were verified by David Laurencio. All specimens reported here represent new county records based on Mount (1975).

The data gathered from this study will provide a better understanding of the status and distribution of amphibians and reptiles in Pike Co., and we hope will promote conservation plans, help establish better land management practices, and be used as baseline data for a long-term monitoring program. Likewise, the results can be used to inform the public of the diversity of amphibian and reptile species in Pike Co.

CAUDATA — SALAMANDERS
